Spectra of Linearized Operators for NLS Solitary Waves

Shu-Ming Chang, Stephen Gustafson, Kenji Nakanishi, Tai-Peng Tsai

Abstract. Nonlinear Schrödinger (NLS) equations with focusing power nonlinearities have solitary wave solutions. The spectra of the linearized operators around these solitary waves are intimately connected to stability properties of the solitary waves, and to the long-time dynamics of solutions of (NLS). We study these spectra in detail, both analytically and numerically.

Key words. Spectrum, linearized operator, NLS, solitary waves, stability.

AMS subject classifications. 35Q55, 35P15.

1 Introduction

Consider the nonlinear Schrödinger equation (NLS) with focusing power nonlinearity,

\[ i\partial_t \psi = -\Delta \psi - |\psi|^{p-1} \psi, \quad (1.1) \]

where \( \psi(t,x) : \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{C} \) and \( 1 < p < \infty \). Such equations arise in many physical settings, including nonlinear optics, water waves, and quantum physics. Mathematically, nonlinear Schrödinger equations with various nonlinearities are studied as basic models of nonlinear dispersive phenomena. In this paper, we stick to the case of a pure power nonlinearity for the sake of simplicity.

For a certain range of the power \( p \) (see below), the NLS (1.1) has special solutions, of the form \( \psi(t,x) = Q(x) e^{it} \). These are called solitary waves. The aim of this paper is to study the spectra of the linearized operators which arise when (1.1) is linearized around solitary waves. The main motivation for this study is that properties of these spectra are intimately related to the problem of the stability (orbital and asymptotic) of these solitary waves, and to the long-time dynamics of solutions of NLS.

Let us begin by recalling some well-known facts about (1.1). Standard references include [4, 29, 30]. Many basic results on the linearized operators we study here were proved by...
The Cauchy (initial value) problem for equation (1.1) is locally (in time) well-posed in $H^1(\mathbb{R}^n)$ if $1 < p < p_{\text{max}}$, where

$$p_{\text{max}} := 1 + 4/(n-2) \quad \text{if } n \geq 3; \quad p_{\text{max}} := \infty \quad \text{if } n = 1, 2.$$ 

Moreover, if $1 < p < p_c$ where

$$p_c := 1 + 4/n,$$

the problem is globally well-posed. For $p \geq p_c$, there exist solutions whose $H^1$-norms go to $\infty$ (blow up) in finite time. In this paper, the cases $p < p_c$, $p = p_c$ and $p > p_c$ are called sub-critical, critical, and super-critical, respectively.

The set of all solutions of (1.1) is invariant under the symmetries of translation, rotation, phase, Galilean transform and scaling: if $\psi(t, x)$ is a solution, then so is

$$\tilde{\psi}(t, x) := \lambda^{2/(p-1)} \psi \left( \lambda^2 t, \lambda Rx - \lambda^2 tv - x_0 \right) \exp \left\{ i \left[ \frac{\lambda Rx \cdot v}{2} - \frac{\lambda^2 tv^2}{4} + \gamma_0 \right] \right\}$$

for any constant $x_0, v \in \mathbb{R}^n$, $\lambda > 0$, $\gamma_0 \in \mathbb{R}$ and $R \in O(n)$. When $p = p_c$, there is an additional symmetry called the “pseudo-conformal transform” (see [30, p.35]).

We are interested here in solutions of (1.1) of the form

$$\psi(t, x) = Q(x) e^{it} \quad \text{(1.2)}$$

Figure 1: Spectra of $\mathcal{L}$, $L_+$ and $L_-$ for $n = 1$. (solid line: purely imaginary eigenvalues of $\mathcal{L}$; dashed line: real eigenvalues of $\mathcal{L}$; dotted line: eigenvalues of $L_+$; dashdot line: eigenvalues of $L_-$)
Figure 2: Spectra of $L$, $L_+$ and $L_-$ restricted to radial functions for $n = 2$.

where $Q(x)$ must therefore satisfy the nonlinear elliptic equation

$$-\Delta Q - |Q|^{p-1}Q = -Q. \tag{1.3}$$

Any such solution generates a family of solutions by the above-mentioned symmetries, called solitary waves. Solitary waves are special examples of nonlinear bound states, which, roughly speaking, are solutions that are spatially localized for all time. More precisely, one could define nonlinear bound states to be solutions $\psi(t, x)$ which are non-dispersive in the sense that

$$\sup_{t \in \mathbb{R}} \inf_{x_0 \in \mathbb{R}^n} \| x |\psi(t, x - x_0)\|_{L^2(\mathbb{R}^n)} < \infty.$$ 

Testing (1.3) with $\overline{Q}$ and $x.\nabla Q$ and taking real parts, one arrives at the Pohozaev identity \cite{22}:

$$\frac{1}{2} \int |Q|^2 = b \frac{1}{p+1} \int |Q|^{p+1}, \quad \frac{1}{2} \int |\nabla Q|^2 = a \frac{1}{p+1} \int |Q|^{p+1} \tag{1.4}$$

where

$$a = \frac{n(p-1)}{4}, \quad b = \frac{n + 2 - (n-2)p}{4}.$$ 

The coefficients $a$ and $b$ must be positive, and hence a necessary condition for existence of non-trivial solutions is $p \in (1, p_{\text{max}})$.

For $p \in (1, p_{\text{max}})$, and for all space dimensions, there exists at least one non-trivial radial solution $Q(x) = Q(|x|)$ of (1.3) (existence goes back to \cite{22}). This solution, called
Figure 3: Spectra of $L$, $L_+$ and $L_-$ restricted to radial functions for $n = 3$.

a nonlinear ground state, is smooth, decreases monotonically as a function of $|x|$, decays exponentially at infinity, and can be taken to be positive: $Q(x) > 0$. It is the unique positive solution. (See [30] for references for the various existence and uniqueness results for various nonlinearities.) The ground state can be obtained as the minimizer of several different variational problems. One such result we shall briefly use later is that, for all $n \geq 1$ and $p \in (1, p_{\text{max}})$, the ground state minimizes the Gagliardo-Nirenberg quotient

$$J[u] := \frac{\left(\int |\nabla u|^2\right)^a (\int u^2)^b}{\int u^{p+1}}$$

among nonzero $H^1(\mathbb{R}^n)$ radial functions (Weinstein [34]).

For $n = 1$, the ground state is the unique $H^1(\mathbb{R})$-solution of (1.3) up to translation and phase [4, p.259, Theorem 8.1.6]. For $n \geq 2$, this is not the case: there are countably infinitely many radial solutions (still real-valued), denoted in this paper by $Q_{0,k,p}(x)$, $k = 0, 1, 2, 3, \ldots$, each with exactly $k$ positive zeros as a function of $|x|$ (Strauss [28]; see also [2]). In this notation, $Q_{0,0,p}$ is the ground state.

There are also non-radial (and complex-valued) solutions, for example those suggested by P. L. Lions [16] with non-zero angular momenta,

$n = 2, \quad Q = \phi(r) e^{im\theta}, \quad$ in polar coordinates $r, \theta$;

$n = 3, \quad Q = \phi(r, x_3) e^{im\theta}, \quad$ in cylindrical coordinates $r, \theta, x_3$,

and similarly defined for $n \geq 4$. Some of these solutions are denoted here by $Q_{m,k,p}$ (see Section 5 for more details).
Figure 4: Spectra of $\mathcal{L}$, $L_+$ and $L_-$ restricted to radial functions for $n = 4$.

We will refer to all the solitary waves generated by $Q_{0,0,p}$ as \textit{nonlinear ground states}, and all others as \textit{nonlinear excited states}. We are not aware of a complete characterization of all solutions of (1.3), or of (1.1). For example, the uniqueness of $Q_{m,k,p}$ with $m,k \geq 1$ is apparently open. Also, we do not know if there are “breather” solutions, analogous to those of the generalized KdV equations. In this paper we will mainly study radial solutions (and in particular the ground state), but we will also briefly consider non-radial solutions numerically in Section 5.

To study the stability of a solitary wave solution (1.2), one considers solutions of (NLS) of the form

$$\psi(t, x) = [Q(x) + h(t, x)]e^{it}.$$  \hfill (1.6)

For simplicity, let $Q = Q_{0,0,p}$ be the ground state for the remainder of this introduction (see Section 5 for the general case). The perturbation $h(t, x)$ satisfies an equation

$$\partial_t h = \mathcal{L}h + \text{(nonlinear terms)}$$  \hfill (1.7)

where $\mathcal{L}$ is the \textit{linearized operator} around $Q$:

$$\mathcal{L}h = -i \left\{(-\Delta + 1 - Q^{p-1})h - \frac{p-1}{2} Q^{p-1}(h + \bar{h}) \right\}.$$  \hfill (1.8)

It is convenient to write $\mathcal{L}$ as a matrix operator acting on $\begin{bmatrix} \text{Re} h \\ \text{Im} h \end{bmatrix}$,

$$\mathcal{L} = \begin{bmatrix} 0 & L_- \\ -L_+ & 0 \end{bmatrix}.$$  \hfill (1.9)
where

\[ L_+ = -\Delta + 1 - pQ^{p-1}, \quad L_- = -\Delta + 1 - Q^{p-1}. \]  \hspace{1cm} (1.10)

Clearly the operators \( L_- \) and \( L_+ \) play a central role in the stability theory. They are self-adjoint Schrödinger operators with continuous spectrum \([1, \infty)\), and with finitely many eigenvalues below 1. In fact, when \( Q \) is the ground state, it is easy to see that \( L_- \) is a nonnegative operator, while \( L_+ \) has exactly one negative eigenvalue (these facts follow from Lemma 2.2 below).

Because of its connection to the stability problem, the object of interest to us in this paper is the spectrum of the non-self-adjoint operator \( \mathcal{L} \). The simplest properties of this spectrum are

1. for all \( p \in (1, p_{\text{max}}) \), 0 is an eigenvalue of \( \mathcal{L} \)
2. the set \( \Sigma_c := \{ ir : r \in \mathbb{R}, |r| \geq 1 \} \) is the continuous spectrum of \( \mathcal{L} \).

(See the next section for the first statement. The second is easily checked.)

It is well-known that the exponent \( p = p_c \) is critical for stability of the ground state solitary wave (as well as for blow-up of solutions). For \( p < p_c \) the ground state is \textit{orbitally stable}, while for \( p \geq p_c \) it is unstable (see [36, 10]). These facts have immediate spectral counterparts: for \( p \in (1, p_c) \), all eigenvalues of \( \mathcal{L} \) are purely imaginary, while for \( p \in (p_c, p_{\text{max}}) \), \( \mathcal{L} \) has at least one eigenvalue with positive real part.

The goal of this paper is to get a more detailed understanding of the spectrum of \( \mathcal{L} \), using both analytical and numerical techniques. This finer information is essential for
understanding the long-time dynamics of solutions of (NLS): for example, for proving asymptotic (rather than simply orbital) stability, for determining rates of relaxation to stable solitary waves, for constructing stable manifolds of unstable solitary waves, etc. (these are highly active areas of current research). Interesting questions with direct relevance to these stability-type problems include:

(i) Can one determine (or estimate) the number and locations of the eigenvalues of $\mathcal{L}$ lying on the segment between 0 and $i$?

(ii) Can $\pm i$, the thresholds of the continuous spectrum $\Sigma_c$, be eigenvalues or resonances?

(iii) Can eigenvalues be embedded inside the continuous spectrum?

(iv) Can the linearized operator have eigenvalues with non-zero real and imaginary parts (this is already known not to happen for the ground state – see the next section – and so we pose this question with excited states in mind).

(v) Are there bifurcations, as $p$ varies, of pairs of purely imaginary eigenvalues into pairs of eigenvalues with non-zero real part (a stability/instability transition)?

Let us now summarize the main results and observations of this paper:

1. **Numerics.** We present numerical computations of the spectra of $\mathcal{L}$, $L_+$ and $L_-$ as functions of $p$, when $Q$ is the ground state solitary wave. Figure 1 is the one-dimensional case. Figures 2, 3, and 4 are the spectra of these operators restricted...
to radial functions, for space dimensions $n = 2, 3, 4$, respectively. For $p \in (1, p_c)$, it is the imaginary parts of the eigenvalues of $L$ which are shown in the figures. For space dimension $n = 2$, Figures 5, 6, and 7 are the spectra restricted to functions of the form $\phi(r)e^{im\theta}$, with $m = 1, 2, 3$, respectively. These pictures shed some light on questions (i), (iv), and (v) above, and to a certain extent on question (ii).

2. **One-dimensional phenomena.** The case $n = 1$ is the easiest case to handle analytically. In Section 3, we undertake a detailed study of the one-dimensional problem, giving rigorous proofs of a number of phenomena observed in Figure 1. One simple such phenomenon is the (actually classical) fact that the eigenvalues of $L_+$ and $L_-$ exactly coincide, with the exception of the first, negative, eigenvalue of $L_+$ (note that this appears to be a strictly one-dimensional phenomenon: the eigenvalues of $L_+$ and $L_-$ are different for $n = 2, 3, 4$, as Figures 2–7 indicate). In fact, we are able to prove sufficiently precise upper and lower bounds on the eigenvalues of $L$ (lying outside the continuous spectrum) to determine their number, and estimate their positions, as functions of $p$ (see Theorem 3.8). We use two basic techniques: an embedding of $L_+$ and $L_-$ into a hierarchy of related operators, and a novel variational problem for the eigenvalues, in terms of a 4-th order self-adjoint differential operator (see Theorem 3.6). In this way, we get a fairly complete answer to question (i) above for $n = 1$.

3. **Variational characterization of eigenvalues.** We present self-adjoint variational formulations of the eigenvalue problem for $L$ in any dimension (see Theorem 2.5), including the novel $n = 1$ formulation mentioned above. In principle, these provide
a means of counting/estimating the eigenvalues of $L$ (and hence addressing question (i) above in higher dimensions), though we only obtain detailed such information for $n = 1$.

4. **Bifurcation at $p = p_c$.** In each of Figures 1–4, a pair of purely imaginary eigenvalues for $p < p_c$ appears to collide at 0 at $p = p_c$, and become a pair of real eigenvalues for $p > p_c$. This is exactly the stability/instability transition for the ground state. We rigorously verify this picture, determining analytically the spectrum near 0 for $p$ near $p_c$, and making concrete a bifurcation picture suggested by M. I. Weinstein (personal communication): see Theorem 2.6. This gives a partial answer to question (v) above. It is worth pointing out that for $n = 1$, the imaginary part of the (purely imaginary) eigenvalue bifurcating for $p < p_c$ is always larger than the third eigenvalue of $L_+$ (the first is negative and the second is zero) – this is proved analytically in Theorem 3.8. For $n \geq 2$, however, they intersect at $p \approx 2.379$ for 2D, $p \approx 2.046$ for 3D, and $p \approx 1.841$ for 4D (see Figures 1–4).

5. **Interlacing property.** A numerical observation: in all the figures, the adjacent eigenvalues of $L$ seem each to bound an eigenvalue of $L_+$ and one of $L_-$ (at least for $p$ small enough). We are able to establish this “interlacing” property analytically in dimension one (see Theorem 3.8).

6. **Threshold resonance.** An interesting fact observed numerically (Figure 1) is that, in the 1D case, as $p \to 3$, one eigenvalue curve converges to $\pm i$, the threshold of the continuous spectrum. One might suspect that, at $p = 3$, $\pm i$ corresponds to a resonance or embedded eigenvalue. It is indeed a resonance: we find an explicit non spatially-decaying “eigenfunction”, and show numerically in Section 3.7 that the corresponding eigenfunctions converges, as $p \to 3$, to this function. This observation addresses question (ii) above for $n = 1$.

7. **Excited states.** In Section 5 we consider the spectra of linearized operators around excited states with non-zero angular momenta. We observe that there are complex eigenvalues which are neither real nor purely imaginary (addressing question (iv) above). These complex eigenvalues may collide into the imaginary axis or the real axis (not at the origin), further addressing question (v) above (see Figures 12–15).

It is worth mentioning some important questions we **cannot** answer:

1. We are so far unable to give precise rigorous estimates on the number and positions of the eigenvalues of $L$ for $n \geq 2$ (question (i) above).

2. We cannot exclude the possible existence of embedded eigenvalues (question (iii) above).

3. We do not know a nice variational formulation for eigenvalues of $L$ when $Q$ is an *excited* state (this problem is also linked to question (i) above).
4. We do not have a complete characterization of solitary waves, or more generally of nonlinear bound states.

We end this introduction by describing some related numerical work. Buslaev-Grikurov [3, 8] study the linearized operators for solitary waves of the following 1D NLS with $p < q$,

$$i\psi_t + \psi_{xx} + |\psi|^p\psi - \alpha|\psi|^q\psi = 0.$$ 

They draw the bifurcation picture for eigenvalues near zero when the parameter $\alpha > 0$ is near a critical value, with the frequency of the solitary wave fixed. This picture is similar to Weinstein’s picture which we study in Section 2.3.

Demanet and Schlag [7] consider the same linearization as us and study the super-critical case $n = 3$ and $p \leq 3$ near 3. In this case, it is numerically shown that both $L_+$ and $L_-$ have no eigenvalues in $(0, 1]$ and no resonance at 1, a condition which implies (see [27]) that $L$ has no purely imaginary eigenvalues in $[-i, 0) \cup (0, i]$ and no resonance at $\pm i$.

We outline the rest of the paper: in Section 2 we consider general results for all dimensions. In Section 3 we consider one dimensional theory. In Section 4 we discuss the numerical methods. In Section 5 we discuss the spectra for excited states with angular momenta.

**Notation:** For an operator $A$, $N(A) = \{ \phi \in L^2 | A\phi = 0 \}$ denotes the nullspace of $A$. $N_g(A) = \bigcup_{k=1}^{\infty} N(A^k)$ denotes the generalized nullspace of $A$. The $L^2$-inner product in $\mathbb{R}^n$ is $(f, g) = \int_{\mathbb{R}^n} \bar{f}g \, dx$.

### 2 General theory

In this section we present results which are valid for all dimensions, for the ground state $Q(x) = Q_{0,0,p}(x)$.

We begin by recalling some well-known results for the linearized operator $L$ defined by (1.8). As observed in [9] and probably known earlier, if $\lambda$ is an eigenvalue, then so are $-\lambda$ and $\pm \bar{\lambda}$. Hence if $\lambda \neq 0$ is real or purely imaginary, it comes in a pair. If it is complex with nonzero real and imaginary parts, it comes in a quadruple. It follows from nonlinear stability and instability results [36, 10] that all eigenvalues are purely imaginary if $p \in (1, p_c)$, and that there is at least one eigenvalue with positive real part when $p \in (p_c, p_{\text{max}})$. It is also known (see e.g. [6]) that the set of isolated and embedded eigenvalues is finite, and the dimensions of the corresponding generalized eigenspaces are finite.

#### 2.1 $L_+,$ $L_-$, and the generalized nullspace of $L$

Here we recall the makeup of the generalized nullspace $N_g(L)$ of $L$. Easy computations give

$$L_+ Q_1 = -2Q, \quad L_- Q = 0,$$

where $Q_1 := \left( \frac{2}{p-1} + x \cdot \nabla \right) Q,$

and

$$L_- x Q = -2\nabla Q, \quad L_+ \nabla Q = 0.$$
In the critical case \( p = p_c \), we also have
\[
L_-(|x|^2Q) = -4Q_1, \quad L_+ \rho = |x|^2Q
\] (2.3)
for some radial function \( \rho(x) \) (for which we do not know an explicit formula in terms of \( Q \)). Denote
\[
\delta_{p, p_c}^p = \begin{cases} 
1 & p = p_c \\
0 & p \neq p_c.
\end{cases}
\] (2.4)
For \( 1 < p < p_{\text{max}} \), the generalized nullspace of \( L \) is given by
\[
N_g(L) = \text{span} \left\{ \begin{bmatrix} 0 \\ Q \end{bmatrix}, \begin{bmatrix} 0 \\ xQ \end{bmatrix}, \delta_{p, p_c}^p \begin{bmatrix} 0 \\ |x|^2Q \end{bmatrix}, \begin{bmatrix} \nabla Q \\ 0 \end{bmatrix}, \begin{bmatrix} Q \end{bmatrix}, \delta_{p, p_c}^p \begin{bmatrix} \rho \end{bmatrix} \right\}.
\] (2.5)
In particular
\[
\dim N_g(L) = 2n + 2 + 2\delta_{p, p_c}^p.
\]
The fact that the vectors on the r.h.s of (2.5) lie in \( N_g(L) \) follows immediately from the computations (2.1)-(2.3). That these vectors span \( N_g(L) \) is established in [35], Theorems B.2 and B.3, which rely on the non-degeneracy of the kernel of \( L_+ \):

**Lemma 2.1** For all \( n \geq 1 \) and \( p \in (1, p_{\text{max}}) \),
\[
N(L_+) = \text{span} \{ \nabla Q \}
\]
This lemma is proved in [35] for certain \( n \) and \( p \) (\( n = 1 \) and \( 1 < p < \infty \), or \( n = 3 \) and \( 1 < p \leq 3 \)), and is completely proved later by a general result of [14]. We present here a direct proof of this lemma, without referring to [14], relying only on oscillation properties of Sturm-Liouville ODE eigenvalue problems. A similar argument (which in the present case, however, applies only for \( p \leq 3 \)) appears in [11], Appendix C. For completeness, we also include some arguments of [35].

**Proof.** We begin with the cases \( n \geq 2 \). Since the potential in \( L_+ \) is radial, any solution of \( L_+ v = 0 \) can be decomposed as \( v = \sum_{k \geq 0} \sum_{j \in \Sigma_k} v_{k,j}(r)Y_{k,j}(\hat{x}) \), where \( r = |x| \), \( \hat{x} = \frac{x}{r} \) is the spherical variable, and \( Y_{k,j} \) denote spherical harmonics: \( -\Delta_{S^{n-1}} Y_{k,j} = \lambda_k Y_{k,j} \) (a secondary multi-index \( j \), appropriate to the dimension, runs over a finite set \( \Sigma_k \) for each \( k \)). Then \( L_+ v = 0 \) can be written as \( A_k v_{k,j} = 0 \), where, for \( k = 0, 1, 2, 3, \ldots \),
\[
A_0 = -\partial_r^2 - \frac{n-1}{r} \partial_r + 1 - pQ^{p-1}(r), \quad A_k = A_0 + \lambda_k r^{-2}, \quad \lambda_k = k(k + n - 2).
\]

Case 1: \( k = 1 \). Note \( \nabla Q = Q'(r)\hat{x} \). Since \( A_1 Q' = 0 \) and \( Q'(r) < 0 \) (monotonicity of the ground state) for \( r \in (0, \infty) \), \( Q'(r) \) is the unique ground state of \( A_1 \) (up to a factor), and so \( A_1 \geq 0 \), \( A_1 \{Q'\}^+ > 0 \).

Case 2: \( k \geq 2 \). Since \( A_k = A_1 + (\lambda_k - \lambda_1) r^{-2} \) and \( \lambda_k > \lambda_1 \), we have \( A_k > 0 \), and hence \( A_k v_k = 0 \) has no nonzero \( L^2 \)-solution.
Case 3: $k = 0$. Note that the first eigenvalue of $A_0$ is negative because $(Q, A_0 Q) = (Q, -(p - 1)Q^p) < 0$. The second eigenvalue is non-negative due to (2.7) and the minimax principle. Hence, if there is a nonzero solution of $A_0 v_0 = 0$, then 0 is the second eigenvalue. By Sturm-Liouville theory, $v_0(r)$ can be taken to have only one positive zero, which we denote by $r_0 > 0$. By (2.1), $A_0 Q = -(p - 1)Q^p$ and $A_0 Q_1 = -2Q$. Hence $(Q^p, v_0) = 0 = (Q, v_0)$. Let $\alpha = (Q(r_0))^{p-1}$. Since $Q'(r) < 0$ for $r > 0$, the function $Q^p - \alpha Q = Q(Q^{p-1} - \alpha)$ is positive for $r < r_0$ and negative for $r > r_0$. Thus $v_0(Q^p - \alpha Q)$ does not change sign, contradicting $(v_0, Q^p - \alpha Q) = 0$. Combining all these cases gives Lemma 2.1 for $n \geq 2$.

Finally, consider $n = 1$. Suppose $L_+ v = 0$. Since $L_+$ preserves oddness and evenness, we may assume $v$ is either odd or even. If it is odd, it vanishes at the origin, and so by linear ODE uniqueness, $v$ is a multiple of $Q'$. So suppose $v$ is even. As in Case 3 above, since $L_+$ has precisely one negative eigenvalue, and has $Q'$ in its kernel, $v(x)$ can be taken to have two zeros, at $x = \pm x_0$, $x_0 \neq 0$. The argument of Case 3 above then applies on $[0, \infty)$ to yield a contradiction.

We complete this section by summarizing some positivity estimates for the operators $L_+$ and $L_-$. These estimates are closely related to the stability/instability of the ground state.

**Lemma 2.2**

\[
L_+ \geq 0, \quad L_-|_{\{Q\}^\perp} > 0 \quad (1 < p < p_{\text{max}}) \tag{2.6}
\]

\[
(Q, L_+ Q) < 0, \quad L_+|_{\{Q\}^\perp} \geq 0 \quad (1 < p < p_{\text{max}}), \tag{2.7}
\]

\[
L_+|_{\{Q\}^\perp} \geq 0 \quad (1 < p \leq p_c) \tag{2.8}
\]

\[
L_+|_{\{Q, x Q\}^\perp} > 0, \quad L_-|_{\{Q_1\}^\perp} > 0 \quad (1 < p < p_c) \tag{2.9}
\]

\[
L_+|_{\{Q, x Q, |x|^2 Q\}^\perp} > 0, \quad L_-|_{\{Q, |x|^2 Q\}^\perp} > 0 \quad (p = p_c). \tag{2.10}
\]

**Proof.** Estimates (2.6) follow from $L_-Q = 0$, $Q > 0$, and the fact that a positive eigenfunction of a Schrödinger operator is its ground state ([23]). Estimates (2.9)–(2.10) are [35] Propositions 2.9 and 2.10. Estimate (2.8) is [35] Proposition 2.7. A refinement of its proof gives the second part of estimate (2.7) (the first part is a simple computation) as follows. Recall the ground state $Q$ is obtained by the minimization problem (1.5). If a minimizer $Q(x)$ is rescaled so that

\[
\frac{\int |\nabla Q|^2}{2a} = \frac{\int Q^2}{2b} = \frac{\int Q^{p+1}}{p+1} = \text{constant} \quad k > 0,
\]

i.e., (1.4) is satisfied, then $Q(x)$ satisfies (1.3). The minimization inequality $\frac{d^2}{d\varepsilon^2} |_{\varepsilon=0} [Q + \varepsilon \eta] \geq 0$ for all real functions $\eta$, is equivalent to

\[
k(\eta, L_+ \eta) \geq \frac{1}{a} (\int \eta \Delta Q)^2 + \frac{1}{b} (\int Q \eta)^2 - (\int Q^p \eta)^2. \tag{2.11}
\]

Thus $(\eta, L_+ \eta) \geq 0$ if $\eta \perp Q^p$. Note that, if $\eta \perp Q$, by (1.3) the right side of (2.11) is positive if $a \leq 1$, i.e. $p \leq p_c$. In this way, we recover (2.8). \qed
2.2 Variational formulations of the eigenvalue problem for $\mathcal{L}$

In this subsection we summarize various variational formulations for eigenvalues of $\mathcal{L}$. The generalized nullspace is given by (2.5). Suppose $\lambda \neq 0$ is a (complex) eigenvalue of $\mathcal{L}$ with corresponding eigenfunction $\begin{bmatrix} u \\ w \end{bmatrix} \in L^2$,

$$
\begin{bmatrix}
0 & L_- \\
-L_+ & 0
\end{bmatrix}
\begin{bmatrix}
u \\ w
\end{bmatrix} = \lambda
\begin{bmatrix}
u \\ w
\end{bmatrix}. 
$$

(2.12)

The functions $u$ and $w$ satisfy

$$
L_+ u = -\lambda w, \quad L_- w = \lambda u.
$$

(2.13)

Therefore

$$
L_- L_+ u = \mu u, \quad \mu = -\lambda^2.
$$

(2.14)

Since $(\mu u, Q) = (L_- L_+ u, Q) = (L_+ u, L_- Q) = 0$ and $\mu \neq 0$, we have $u \perp Q$.

Denote by $\Pi$ the $L^2$-orthogonal projection onto $Q^\perp$. We can write $L_+ u = \Pi L_+ u + \alpha Q$. Eq. (2.14) implies $L_- \Pi L_+ u = \mu u$ and hence, using $u \perp Q$ and (2.6), $\Pi L_+ u = L_-^{-1} \mu u$. Thus

$$
(u, Q) = 0, \quad L_+ u = \mu L_-^{-1} u + \alpha Q.
$$

(2.15)

Since (2.14) is also implied by Eq. (2.15), these two equations are equivalent.

If $Q(x)$ is a general solution of (1.3), $\mu = -\lambda^2$ may not be real. However, it must be real for the nonlinear ground state $Q = Q_{0,0,p}$. This fact is already known (see [25]). We will give a different proof.

**Claim.** For $Q = Q_{0,0,p}$, every eigenvalue $\mu$ of (2.14) is real.

**Proof.** Multiply (2.13) by $\bar{u}$ and $\bar{w}$ respectively and integrate. Then we get

$$
(u, L_+ u) = -\lambda (u, w), \quad (w, L_- w) = \lambda (w, u) = \lambda \overline{(u, w)}.
$$

(2.16)

Taking the product, we get

$$
(u, L_+ u)(w, L_- w) = -\lambda^2 |(u, w)|^2 = \mu |(u, w)|^2.
$$

If $\mu \neq 0$, $w$ is not a multiple of $Q$, and so by (2.6), $(w, L_- w) > 0$. Hence $(u, w) \neq 0$ by (2.16). Thus

$$
\mu = \frac{(u, L_+ u)(w, L_- w)}{|(u, w)|^2} \in \mathbb{R}.
$$

□

This argument does not work when $Q$ is an excited state, since $(u, w)$ may be zero (see e.g. [33, Eq.(2.63)]). The fact $\mu \in \mathbb{R}$ implies that eigenvalues $\lambda$ of $\mathcal{L}$ are either real or purely imaginary. Thus $\mathcal{L}$ has no complex eigenvalues with nonzero real and imaginary parts. This is not the case for excited states (see Section 5, also [33]).
The proof of reality of \( \mu \) in [25] uses the following formulation. For the nonlinear ground state \( Q, L \) is nonnegative and the operator \( L^{1/2} \) is defined on \( L^2 \) and invertible on \( Q^\perp \). A nonzero \( \mu \in \mathbb{C} \) is an eigenvalue of (2.14) if and only if it is also an eigenvalue of the following problem:

\[
L^{1/2}L_+L^{1/2}g = \mu g,
\]

with \( g = L_-^{-1/2}u \). The operator \( L_-^{1/2}L_+L_-^{1/2} \) already appeared in [32]. Since it can be realized as a self-adjoint operator, \( \mu \) must be real.

Furthermore, the eigenvalues of \( L_-^{1/2}L_+L_-^{1/2} \) can be counted using the minimax principle. Note that \( Q \) is an eigenfunction with eigenvalue 0. For easy comparison with other formulations, we formulate the principle on \( Q^\perp \). Let

\[
\mu_j := \inf_{g \in Q, g_k, k=1, \ldots, j-1} \frac{(g, L_-^{1/2}L_+L_-^{1/2}g)}{(g, g)}, \quad (j = 1, 2, 3, \ldots)
\]

with a suitably normalized minimizer denoted by \( g_j \) (if it exists – the definition terminates once a minimizer fails to exist). The corresponding definition for (2.15) is

\[
\mu_j := \inf_{u \in Q, (u, L_-^{-1}u_k) = 0, k=1, \ldots, j-1} \frac{(u, L_+u)}{(u, L_-^{-1}u)}, \quad (j = 1, 2, 3, \ldots)
\]

with a suitably normalized minimizer denoted by \( u_j \) (if it exists). In fact, the minimizer \( u_j \) satisfies

\[
L_+u_j = \mu_jL_-^{-1}u_j + \alpha_jQ + \beta_1L_-^{-1}u_1 + \cdots + \beta_{j-1}L_-^{-1}u_{j-1},
\]

for some Lagrange multipliers \( \beta_1, \ldots, \beta_{j-1} \). Testing (2.20) with \( u_k \) with \( k < j \), we get

\[
(u_k, \beta_kL_-^{-1}u_j) = (u_k, L_+u_j) = (L_+u_k, u_j) = 0
\]

by (2.20) for \( u_k \) and the orthogonality conditions. Thus \( \beta_k = 0 \) and \( L_+u_j = \mu_jL_-^{-1}u_j + \alpha_jQ \) and hence \( u_j \) satisfies (2.15).

**Lemma 2.3** The eigenvalues of (2.18) and (2.19) are the same, and

- if \( 1 < p < p_c \) : \( \mu_1 = \cdots = \mu_n = 0, \quad \mu_{n+1} > 0 \).
- if \( p = p_c \) : \( \mu_1 = \cdots = \mu_{n+1} = 0, \quad \mu_{n+2} > 0 \).
- if \( p_c < p < p_{\max} \) : \( \mu_1 < 0, \quad \mu_2 = \cdots = \mu_{n+1} = 0, \quad \mu_{n+2} > 0 \).

The 0-eigenspaces are \( \text{span} L_-^{-1/2}\{\nabla Q, \delta_{pc}Q_1\} \) for (2.18) and \( \text{span}\{\nabla Q, \delta_{pc}Q_1\} \) for (2.19), where \( \delta_{pc} \) is defined in (2.4).

**Proof.** The eigenvalues of (2.18) and (2.19) are seen to be the same by taking \( g = L_-^{-1/2}u \) up to a factor. By estimate (2.8), \( \mu_1 \geq 0 \) for \( p \in (1, p_c] \). For \( p \in (p_c, p_{\max}) \), using (1.4), \( \Pi Q_1 = Q_1 - \frac{(Q_1, Q)}{(Q, Q)}Q \), and elementary computations (such as (2.22) below), one finds

\[
(\Pi Q_1, L_+\Pi Q_1) = \frac{n^2(p-1)}{4}(p_c-p)\frac{1}{p+1} \int Q^{p+1}
\]
which is negative for $p > p_c$. Thus $\mu_1 < 0$. By estimate (2.7), $\mu_2 \geq 0$ for $p \in (1, p_{\text{max}})$.

It is clear that $u = \frac{\partial}{\partial x_j} Q$, $j = 1, \ldots, n$, provides $n$ 0-eigenfunctions. For $p = p_c$, another 0-eigenfunction is $u = Q_1$ since $Q_1 \perp Q$ (see again (2.22) below), $L^{-1}_- \nabla Q = -\frac{1}{2} x Q$, and $(Q_1, L_+ Q_1) = 0$. It remains to show that $\mu_{n+1} > 0$ for $p \in (1, p_c)$ and $\mu_{n+2} > 0$ for $p \in [p_c, p_{\text{max}})$. If $\mu_{n+2} = 0$ for $p \in (p_c, p_{\text{max}})$, the argument after (2.20) shows the existence of a function $u_{n+2} \neq 0$ satisfying

$$L_+ u_{n+2} = \alpha Q \quad \text{for some } \alpha \in \mathbb{R}, \quad u_{n+2} \perp Q, \quad L^{-1}_- u_1, \quad L^{-1}_- \nabla Q = -\frac{1}{2} x Q.$$ 

By Lemma 2.1, $u_{n+2} + \frac{\alpha}{2} Q_1 = c \cdot \nabla Q$ for some $c \in \mathbb{R}^d$. The orthogonality conditions imply $u_{n+2} = 0$. The cases $p \in (1, p_c]$ are proved similarly. \hfill \Box

**Remark 2.4** The formulation (2.19) for $\mu_1$ has been used for the stability problem, see e.g. [30, p.73, (4.1.9)], which can be used to prove that $\mu_1 < 0$ if and only if $p \in (p_c, p_{\text{max}})$ by a different argument. The later fact also follows from [35, 10] indirectly.

We summarize our previous discussion in the following theorem.

**Theorem 2.5** Let $Q(x)$ be the unique positive radial ground state solution of (1.3), and let $L$, $L_+$ and $L_-$ as in (1.8) and (1.10). The eigenvalue problems (2.14), (2.15), and (2.17) for $\mu \neq 0$ are equivalent, and the eigenvalues $\mu$ must be real. These eigenvalues can be counted by either (2.18) or (2.19). $\mu_1 < 0$ if and only if $p \in (p_c, p_{\text{max}})$. Furthermore, all eigenvalues of $L$ are purely imaginary except for an additional real pair when $p \in (p_c, p_{\text{max}})$.

The last statement follows from the relation $\mu = -\lambda^2$ in (2.14).

### 2.3 Spectrum near 0 for $p$ near $p_c$

We now consider eigenvalues of $L$ near 0 when $p$ is near $p_c$. It was suggested by M.I. Weinstein that as $p$ approaches $p_c$ from below, a pair of purely imaginary eigenvalues will collide at the origin, and split into a pair of real eigenvalues for $p > p_c$. Although this picture is well-known, there does not seem to be a written proof. In the following theorem and corollary we prove this picture rigorously and identify the leading terms of the eigenvalues and eigenfunctions.

**Theorem 2.6** There are small constants $\mu_*, \varepsilon > 0$ and $\varepsilon_* > 0$ so that for every $p \in (p_c - \varepsilon_*, p_c + \varepsilon_*)$, there is a solution of

$$L_+ L_- w = \mu w$$

of the form

$$w = w_0 + (p - p_c)^2 g, \quad w_0 = Q + a(p - p_c) |x|^2 Q, \quad g \perp Q,$$

$$\mu = 8a(p - p_c) + (p - p_c)^2 \eta, \quad a = a(p) = \frac{n(Q_1, Q^p)}{4(Q_1, x^2 Q)} < 0,$$

with $\|g\|_{L^2}$, $|\eta|$, $|a|$ and $1/|a|$ uniformly bounded in $p$. Moreover, for $p \neq p_c$, this is the unique solution of (2.21) with $0 < |\mu| \leq \mu_*$. 

15
Proof. Set \( \varepsilon := p - p_c \). Computations yield

\[
(Q_1, Q) = \left(\frac{2}{p-1} - \frac{n}{2}\right) (Q, Q) = -\frac{\varepsilon n}{2(p-1)} (Q, Q), \tag{2.22}
\]

\[
(Q_1, Q^p) = -\frac{1}{p-1} (L_+ Q, Q_1) = -\frac{1}{p-1} (Q, L_+ Q_1) = \frac{2}{p-1} (Q, Q), \tag{2.23}
\]

and

\[
(Q_1, |x|^2 Q) = \left(\frac{2}{p-1} - \frac{n + 2}{2}\right) (Q, |x|^2 Q) = -(1 + \frac{\varepsilon n}{2(p-1)}) (Q, |x|^2 Q). \tag{2.24}
\]

Since by (2.21) with \( \mu \neq 0 \),

\[
(Q_1, w) = \mu^{-1} (Q_1, L_+ L_- w) = \mu^{-1} (L_- L_+ Q_1, w) = 0,
\]

we require the leading term \((Q_1, w_0) = 0\), which decides the value of \( a \) using (2.22) and (2.24). Thus we also need \((Q_1, g) = 0\). That \( a < 0 \) (at least for \( \varepsilon \) sufficiently small) follows from (2.23) and (2.24).

Using the computations

\[
L_- |x|^2 Q = [L_-, |x|^2] Q = -4x \cdot \nabla Q - 2nQ = -4Q_1 - \frac{2n}{p-1} \varepsilon Q \tag{2.25}
\]

and

\[
L_+ Q = [L_- - (p-1)Q^{p-1}] Q = -(p-1)Q^p,
\]

we find

\[
L_+ L_- w_0 = a \varepsilon L_+ [-4Q_1 - \frac{2n}{p-1} \varepsilon Q] = a \varepsilon [8Q + 2n \varepsilon Q^p].
\]

Thus \( \mu = 8a \varepsilon + o(\varepsilon) \) and we need to solve

\[
0 = [L_+ L_- - 8a \varepsilon - \varepsilon^2 \eta] [w_0 + \varepsilon^2 g]
\]

which yields our main equation for \( g \) and \( \eta \):

\[
L_+ L_- g = 8a^2 (|x|^2 Q) - 2an(Q^p) + \eta w_0 + (8a \varepsilon + \varepsilon^2 \eta) g. \tag{2.26}
\]

Recall that on radial functions (we will only work on radial functions here)

\[
\ker[(L_+ L_-)^*] = \ker[L_- L_+] = \text{span}\{Q_1\}.
\]

Let \( P \) denote the \( L^2 \)-orthogonal projection onto \( Q_1 \) and \( \bar{P} := 1 - P \). It is necessary that

\[
P[8a^2 (|x|^2 Q) - 2an(Q^p) + \eta w_0 + (8a \varepsilon + \varepsilon^2 \eta) g] = 0
\]

for (2.26) to be solvable. This solvability condition holds since \((Q_1, g) = (Q_1, w_0) = 0\), and, using the relations (2.24) and (2.23), \((Q_1, 8a^2(|x|^2 Q) - 2an(Q^p)) = 0\).
Consider the restriction (on radial functions)
\[ T = L_+ L_- : \ker L_- \parallel = Q^\perp \longrightarrow \text{Ran}(\bar{P}) = Q_1^\perp. \]
Its inverse \( T^{-1} = (L_-)^{-1}(L_+)^{-1} \) is bounded because \((L_+)^{-1} : Q_1^\perp \rightarrow Q^\perp \) and \((L_-)^{-1} : Q^\perp \rightarrow Q^\perp \) are bounded. So our strategy is to solve (2.26) as
\[ g = T^{-1} \bar{P}[8a^2(|x|^2 Q) - 2an(Q^p) + \eta w_0 + (8a\varepsilon + \varepsilon^2 \eta)g] \]
by a contraction mapping argument, with \( \eta \) chosen so that \((Q_1,g) = 0. \) Specifically, we define a sequence \( g_0 = 0, \eta_0 = 0, \) and
\[ g_{k+1} = \bar{P}T^{-1} \bar{P}[8a^2(|x|^2 Q) - 2an(Q^p) + \eta_k w_0 + (8a\varepsilon + \varepsilon^2 \eta_k)g_k], \]
\[ \eta_{k+1} = -\frac{1}{(Q_1, T^{-1} w_0)} (Q_1, T^{-1} \bar{P}[8a^2(|x|^2 Q) - 2an(Q^p) + (8a\varepsilon + \varepsilon^2 \eta_k)g_k]). \]
We need to check \((Q_1, T^{-1} w_0)\) is of order one. Since \( w_0 = Q + O(\varepsilon) \) and \( L_+ Q_1 = -2Q, \) we have \((L_+)^{-1} w_0 = -\frac{1}{2} \Pi Q_1 + O(\varepsilon) \) where \( \Pi \) denotes the orthogonal projection onto \( Q^\perp. \)
Thus, using (2.25) and (2.22),
\[ (Q_1, T^{-1} w_0) = -\frac{1}{2} (Q_1, (L_-)^{-1} \Pi Q_1) + O(\varepsilon) \]
\[ = \frac{1}{8} (Q_1, \Pi |x|^2 Q) + O(\varepsilon) = \frac{1}{8} (Q_1, |x|^2 Q) + O(\varepsilon), \]
which is of order one because of (2.24). One may then check that \( N_k := \|g_{k+1} - g_k\|_{L^2} + \varepsilon^{1/2} |\eta_{k+1} - \eta_k| \) satisfies \( N_{k+1} \leq C \varepsilon^{1/2} N_k, \) and hence \((g_k, \eta_k)\) is indeed a Cauchy sequence.

Finally, the uniqueness follows from the invariance of the total dimension of generalized eigenspaces near 0 under perturbations. \( \square \)

**Remark 2.7** To understand heuristically the leading terms in \( w \) and \( \mu, \) consider the following analogy. Let \( A_\varepsilon = \begin{bmatrix} 0 & 1 \\ 0 & \varepsilon \end{bmatrix}, \) which corresponds to \( L_+ L_- \). One has \( A_\varepsilon \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ \varepsilon \end{bmatrix}, \)
\( A_\varepsilon \begin{bmatrix} \varepsilon \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ \varepsilon \end{bmatrix} \) and \( A_\varepsilon \begin{bmatrix} \varepsilon \\ 1 \end{bmatrix} = \varepsilon \begin{bmatrix} 1 \\ \varepsilon \end{bmatrix}. \) The vectors \( \begin{bmatrix} 1 \\ \varepsilon \end{bmatrix}, \begin{bmatrix} \varepsilon \\ 0 \end{bmatrix} \) and \( \begin{bmatrix} \varepsilon \\ 1 \end{bmatrix} \) correspond to \( Q, |x|^2 Q \) and \( w, \) respectively.

The theorem yields an eigenvalue \( \mu \) with the same sign as \( p_c - p. \) Since the eigenvalues of \( \mathcal{L} \) are given by \( \lambda = \pm \sqrt{-\mu}, \) we have the following corollary.

**Corollary 2.8** With notations as in Theorem 2.6, \( \mathcal{L} \) has a pair of eigenvalues \( \lambda = \pm \sqrt{-\mu} = \pm \sqrt{8a|p - p_c|} - (p - p_c)^2 \eta \) with corresponding eigenvectors \( \begin{bmatrix} u \\ w \end{bmatrix} \) solving (2.12) and
\[ u = \lambda^{-1} L_- w = \mp \sqrt{2|a|(|p - p_c|)} Q_1 + O((p - p_c)^{3/2}). \]

When \( p \in (p_c - \varepsilon, p_c) \) (stable case), \( \lambda \) and \( u \) are purely imaginary.

When \( p \in (p_c, p_c + \varepsilon_*) \) (unstable case), \( \lambda \) and \( u \) are real.

In deriving the leading term of \( u \) we have used (2.25). We solved for \( w \) before \( u \) simply because \( w \) is larger than \( u. \)
3 One dimensional theory

In this section we focus on the one dimensional theory. For $n=1$, the ground state $Q(x)$ has an explicit formula for all $p \in (1, \infty)$,

$$Q(x) = c_p \cosh^{\beta}(x/\beta), \quad c_p := \left(\frac{p+1}{2}\right)^{1/p}, \quad \beta := \frac{2}{p-1},$$

(3.1)

where $\cosh(x)$ denotes the hyperbolic cosine function $\cosh(x)$. The function $Q(x)$ satisfies (1.3) and is the unique $H^1(\mathbb{R})$-solution of (1.3) up to translation and phase [4, p.259, Theorem 8.1.6].

3.1 Eigenfunctions of $L_+$ and $L_-$

We first consider eigenvalues and eigenfunctions of $L_+$ and $L_-$. For $n=1$,

$$L_+ = -\partial^2_{xx} + 1 - pQ^{p-1}, \quad L_- = -\partial^2_{xx} + 1 - Q^{p-1}.$$  

(3.2)

By (3.1), these operators are both of the form

$$-\partial^2_{xx} + 1 - C \sech^2(x/\beta).$$

Such operators have essential spectrum $[1, \infty)$, and finitely many eigenvalues below 1. A lot of information about such operators is available in the classical book [31], p. 103:

- all eigenvalues are simple, and can be computed explicitly, as zeros and poles of an explicit meromorphic function;
- all eigenfunctions can be expressed in terms of the hypergeometric function.

We begin by presenting another way to derive the eigenvalues, as well as different formulas for the eigenfunctions. We will not prove right here that this set contains all of the eigenvalues/eigenfunctions. This fact is a consequence of the more general Theorem 3.4, proved later (and see also [31]).

Define

$$\lambda_m := 1 - k_m^2, \quad k_m := \frac{p + 1}{2} - \frac{m(p-1)}{2},$$

$$p_m := \frac{m+1}{m-1} \quad \text{for } m > 1, \quad p_1 = \infty.$$  

(3.3)

The following theorem agrees with the numerical observation Figure 1.

**Theorem 3.1** In one space dimension with $1 < p < \infty$, let $Q(x)$ be defined by (3.1), $L_+$ and $L_-$ be defined by (3.2), and $\lambda_m$ be defined by (3.3). Suppose for $j \in \mathbb{Z}^+$,

$$p_{j+1} \leq p < p_j.$$  

(3.4)
Then the operator $L_+$ has eigenvalues $\lambda_m$, $m = 0, 1, 2, 3, \ldots, j$, with eigenfunctions $\varphi_m$ to be defined by (3.6) and (3.7), which are odd for odd $m$ and even for even $m$. The operator $L_-$ has eigenvalues $\lambda_m$, $m = 1, 2, 3, \ldots, j$, with eigenfunctions $\psi_m$ to be defined by (3.9), which are odd for even $m$ and even for odd $m$.

In particular, all eigenvalues of $L_-$ are eigenvalues of $L_+$, and $L_+$ always has one more eigenvalue ($\lambda_0$) than $L_-$. Note that $\lambda_0 < 0 = \lambda_1$ and $\lambda_m > 0$ for $2 \leq m \leq j$.

**Proof.** We first consider even eigenfunctions of $L_+$. By the explicit formula (3.1) of $Q(x)$, we have

\[
Q^{p-1} = \frac{p+1}{2} \text{ch}^{-2}(x/\beta),
\]
\[
Q_x = -Q \tanh(x/\beta),
\]
\[
Q_x^2 = Q^2(1 - \frac{1}{\text{ch}^2}) = Q^2(1 - \frac{2}{p+1} Q^{p-1}).
\]

Thus

\[
Q^{-k} \partial_{xx} Q^k = (k^2 - k)Q^{-2}Q_x^2 + kQ^{-1}Q_{xx} = (k^2 - k)(1 - \frac{2}{p+1} Q^{p-1}) + k(1 - Q^{p-1}).
\]

By (3.2),

\[
Q^{-k} L_+ Q^k = -(k^2 - k)(1 - \frac{2}{p+1} Q^{p-1}) - k(1 - Q^{p-1}) + 1 - pQ^{p-1}
\]
\[
= f_p(k)Q^{p-1} + (1 - k^2),
\]

where

\[
f_p(k) = \frac{2}{p+1} (k + p)(k - \frac{p+1}{2}).
\]

Let

\[
k_0 = \frac{p+1}{2}, \quad \varphi_0 = Q^{k_0}, \quad \lambda_0 = 1 - k_0^2 < 0.
\]

We have $f_p(k_0) = 0$. Thus $L_+ \varphi_0 = \lambda_0 \varphi_0$.

If $1 < p < 3$, let

\[
k_2 = k_0 - (p-1) = \frac{3-p}{2}, \quad \varphi_2 = Q^{k_2} + c_0^2 Q^{k_0}, \quad \lambda_2 = 1 - k_2^2.
\]

Here and after, $c_m$ denotes constants to be chosen. We have $k_2 > 0$, $0 < \lambda_2 < 1$ for $p < 3$ and, by (3.5),

\[
L_+ \varphi_2 = [f_p(k_2)Q^{k_0} + \lambda_2 Q^{k_2}] + c_0^2 \lambda_0 Q^{k_0}.
\]

If we choose

\[
c_0^2 = \frac{f_p(k_2)}{\lambda_2 - \lambda_0} = \frac{f_p(k_2)}{k_0^2 - k_2^2} = -\frac{3+p}{2(p+1)},
\]

19
we have
\[ L_+ \varphi_2 = \lambda_2 \varphi_2, \quad \varphi_2 = Q^{k_2} + \frac{f_p(k_2)}{\lambda_2 - \lambda_0} Q^{k_0}. \]

If \(1 < p < 5/3\), let
\[ k_4 = k_2 - (p - 1) = \frac{5 - 3p}{2}, \quad \varphi_4 = Q^{k_4} + c_2^4 Q^{k_2} + c_0^4 Q^{k_0}, \quad \lambda_4 = 1 - k_4^2. \]
We have \(k_4 > 0\) and
\[ L_+ \varphi_4 = [f_p(k_1) Q^{k_2} + \lambda_4 Q^{k_4}] + c_2^4 [f_p(k_2) Q^{k_0} + \lambda_2 Q^{k_2}] + c_0^4 \lambda_0 Q^{k_0}. \]
If we choose
\[ c_2^4 = \frac{f_p(k_1)}{\lambda_4 - \lambda_2}, \quad c_0^4 = \frac{c_2^4 \cdot f_p(k_2)}{\lambda_4 - \lambda_0}, \]
we have
\[ L_+ \varphi_4 = \lambda_4 \varphi_4, \quad \varphi_4 = Q^{k_4} + \frac{f_p(k_1)}{\lambda_4 - \lambda_2} Q^{k_2} + \frac{f_p(k_1)}{\lambda_4 - \lambda_2} \cdot \frac{f_p(k_2)}{\lambda_4 - \lambda_0} Q^{k_0}. \]

For general integer \(m \geq 0\), let \(k_m\) be defined by (3.3), which is positive if \(m = 0, 1\), or if \(p < \frac{m + 1}{m + 1}\). If \(k_2j > 0\), the \(j\)-th even eigenfunction of \(L_+\) is given by
\[ \varphi_{2j} = \sum_{m=0}^{j} c_{2m}^{2j} Q^{k_{2m}}, \quad (3.6) \]
with eigenvalue \(\lambda_{2j} = 1 - k_{2j}^2\) and
\[ c_{2j}^2 = 1, \quad c_{2m}^{2j} = c_{2m+2}^{2j} \cdot \frac{f_p(k_{2m+2})}{\lambda_{2j} - \lambda_{2m}}, \quad (0 \leq m \leq j - 1). \]

We next consider odd eigenfunctions of \(L_+\). Since
\[ \partial_x^2 (Q^k)_x = 3k(k - 1)Q^{k-2}Q_x Q_{xx} + k(k - 1)(k - 2)Q^{k-3}Q_x^2 + kQ^{k-1}Q_{xxx}, \]
we have
\[ [(Q^k)_x]^{-1} \partial_x^2 (Q^k)_x = 3(k - 1)Q^{-1}Q_{xx} + (k - 1)(k - 2)Q^{-2}Q_x^2 + Q^{-1}Q_{xxx} \]
\[ = 3(k - 1)(1 - Q^{-1}) + (k - 1)(k - 2)(1 - \frac{2}{p + 1}Q^{-1}) + (1 - pQ^{-1}) \]
\[ = k^2 + Q^{-1}[-3k + 3 - \frac{2}{p + 1}(k^2 - 3k + 2) - p]. \]
Thus
\[ [(Q^k)_x]^{-1} L_+ (Q^k)_x = g_p(k) Q^{p-1} + 1 - k^2, \]
where
\[ g_p(k) = \frac{2k + 3p - 1}{p + 1}(k - 1). \]

20
The only zero of \( g_p(k) = 0 \) with \( k > 0 \) is \( k = k_1 = 1 \). The first odd eigenfunction of \( L_+ \) is given by
\[
\varphi_1 = (Q^{k_1})_x, \quad k_1 = 1, \quad L_+ \varphi_1 = 0.
\]
If \( k_{2j-1} > 0 \), the \( j \)-th odd eigenfunction of \( L_+ \) is
\[
\varphi_{2j-1} = \sum_{m=1}^{j} c_{2m-1}^{2j-1} (Q^{k_{2m-1}})_x, \tag{3.7}
\]
with eigenvalue \( \lambda_{2j-1} = 1 - k_{2j-1}^2 \) and coefficients
\[
c_{2j-1}^{2j-1} = 1, \quad c_{2m-1}^{2j-1} = c_{2m+1}^{2j-1} \cdot \frac{g_p(k_{2m+1})}{\lambda_{2j-1} - \lambda_{2m-1}}, \quad (0 < m \leq j - 1).
\]

In conclusion, if \( p_{m+1} \leq p < p_m \) (\( p_1 = \infty \)), we have found \( m + 1 \) eigenvalues for \( L_+ \).

We now consider \( L_- \), which is similar. We have
\[
Q^{-k}L_-Q^k = f_p^-(k)Q^{p-1} + (1 - k^2), \tag{3.8}
\]
where
\[
f_p^-(k) = f_p(k) + p - 1 = \frac{1}{p+1}(k-1)(2k+p+1),
\]
\[
g_p^-(k) = g_p(k) + p - 1 = \frac{1}{p+1}(k+p)(2k+p-3).
\]
The only zero for \( f_p^- \) is \( k = 1 = k_1 \). The only zero for \( g_p^- \) is \( k = \frac{3-p}{2} = k_2 \). Thus the first even eigenfunction for \( L_- \) is \( Q^{k_1} \) and the first odd eigenfunction for \( L_- \) is \( (Q^{k_2})_x \). By an argument similar to those for \( L_+ \), if \( p_{m+1} \leq p < p_m \), we can find \( m \) eigenfunctions \( \psi_1, \ldots, \psi_m \) for \( L_- \) of the form
\[
\psi_{2j-1} = \sum_{m=1}^{j} d_{2m-1}^{2j-1} Q^{k_{2m-1}}, \quad \psi_{2j} = \sum_{m=1}^{j} d_{2m}^{2j} (Q^{k_{2m}})_x, \tag{3.9}
\]
with eigenvalues \( \lambda_1, \ldots, \lambda_m \). The coefficients \( d_m^j \) can be defined recursively in a similar fashion. Note that these thresholds for the exponent \( p \) are the same as those for \( L_+ \). In particular, the number of eigenvalues of \( L_- \) is always that of \( L_+ \) minus one. This completes the proof of the theorem. \[ \square \]
3.2 Connection between $L_+$ and $L_-$ and their factorizations

In light of Theorem 3.1, it is natural to ask why all eigenvalues of $L_-$ are also eigenvalues of $L_+$. Is there a simple connection between their eigenfunctions? In this section we prove this is indeed so.

We first look for an operator $U$ of the form

$$U = \partial_x + R(x), \quad (\text{so } U^* = -\partial_x + R(x)),$$

such that

$$L_- U = U L_+, \quad (\text{so } U^* L_- = L_+ U^*). \quad (3.10)$$

It turns out that there is a unique choice of $R(x)$:

$$R(x) = \frac{p+1}{2} Q_x = \frac{p+1}{2} \tanh\left(\frac{(p-1)x}{2}\right).$$

In fact, with this choice of $R(x)$,

$$U = \varphi_0 \partial_x \varphi_0^{-1}, \quad (\text{so } U^* = -\varphi_0^{-1} \partial_x \varphi_0), \quad (3.11)$$

where $\varphi_0 = Q^{p+1} \frac{x}{2}$ is the ground state of $L_+$, and is considered here as a multiplication operator: $U f = \varphi_0 \partial_x (\varphi_0^{-1} f)$.

Suppose now $\psi$ is an eigenfunction of $L_-$ with eigenvalue $\lambda$: $L_- \psi = \lambda \psi$. By (3.10),

$$0 = U^* (L_- - \lambda) \psi = (L_+ - \lambda) U^* \psi.$$

Thus $U^* \psi$ is an eigenfunction of $L_+$ with same eigenvalue $\lambda$ (provided $U^* \psi \in L^2$). Therefore, the map

$$\psi \mapsto U^* \psi$$

sends an eigenfunction of $L_-$ to an eigenfunction of $L_+$ with same eigenvalue. This map is not onto because $U^*$ is not invertible. Specifically, the ground state $\varphi_0$ is not in the range. In fact, $U \varphi_0 = \varphi_0 \partial_x \varphi_0^{-1} \varphi_0 = 0$. If $\varphi_0 = U^* \psi$, then $(\varphi_0, \varphi_0) = (\varphi_0, U^* \psi) = (U \varphi_0, \psi) = 0$, a contradiction. We summarize our finding as the following proposition.

**Proposition 3.2** Under the same assumptions and notation as Theorem 3.1, the eigenfunctions $\varphi_m$ and $\psi_m$ of $L_+$ and $L_-$ satisfy

$$\varphi_m = U^* \psi_m, \quad (m = 1, \ldots, j),$$

up to constant factors. Note that $U^*$ sends even functions to odd functions and vice versa.

**Proof.** We only need to verify that $U^* \psi_m \in L^2$. This is the case since $U^* = -\partial_x + \frac{p+1}{2} \tanh(x/\beta)$, $\psi_m(x)$ are sums of powers of $Q$ and $Q_x$, and that $\tanh(x/\beta)$, $Q_x/Q$, and $Q_{xx}/Q_x$ are bounded. □
Analogous to the definition of $U$, we define

$$S := Q \partial_x Q^{-1} = \partial_x - \frac{Q_x}{Q}, \quad \text{(so } S^* = -Q^{-1} \partial_x Q).$$

(3.12)

Clearly $SQ = 0$. Recall that $\lambda_0$ is the first eigenvalue of $L_+$ with eigenfunction $\varphi_0$. Hence $L_+ - \lambda_0$ is a nonnegative operator. In fact we have the following factorizations.

Lemma 3.3 Let $U$ and $S$ be defined by (3.11) and (3.12), respectively. One has

$$L_+ - \lambda_0 = U^* U, \quad L_- - \lambda_0 = UU^*.$$  

(3.13)

Moreover, $SS^* > 0$.

The last fact is due to $SS^* = L_- + \frac{2(p-1)}{p+1} Q^{p-1}$. The formula $L_- = S^* S$ was known, see e.g. [30, p.73, (4.1.8)].

3.3 Hierarchy of Operators

In this subsection we generalize Theorem 3.1 and Lemma 3.3 to a family of operators containing $L_+$ and $L_-$. As a reminder, we have

$$Q''/Q = 1 - Q^{p-1}, \quad (Q'/Q)^2 = 1 - \frac{2}{p+1} Q^{p-1},$$

$$ (Q'/Q)' = Q''/Q - (Q'/Q)^2 = -\frac{p-1}{p+1} Q^{p-1}. $$

(3.15)

Let $S(a) := Q^a \partial_x Q^{-a}$. We have

$$S(a) = \partial_x - aQ'/Q, \quad S(a)^* = -\partial_x - aQ'/Q,$$

$$S(a)^* S(a) = -\partial_x^2 + a^2 - a \left\{ a + \frac{p-1}{2} \right\} \frac{2}{p+1} Q^{p-1}. $$

(3.16)

Define the following hierarchy of operators:

$$S_j := S(k_j), \quad \text{where recall } \quad k_j = 1 - (j-1) \frac{p-1}{2},$$

$$L_j := S_{j-1} S_{j-1}^* + \lambda_{j-1} = S_j^* S_j + \lambda_j, \quad \text{where recall } \quad \lambda_j = 1 - k_j^2.$$  

(3.17)

Then we have

$$S_0 = U, \quad S_1 = S, \ldots$$

$$L_0 = L_+, \quad L_1 = L_-, \quad L_2 = SS^*, \ldots$$

$$S_j L_j = L_{j+1} S_j, \quad L_j S_j^* = S_j^* L_{j+1}. $$

(3.18)
More explicitly,

$$L_j = -\partial_x^2 + 1 - k_{j-1}k_j \frac{2}{p+1} Q^{p-1}. \quad (3.19)$$

Note that $j$ here can be any real number.

Recall the definition $p_j := 1 + 2/(j - 1)$ for $j > 1$, and set $p_j = \infty$ for $j \leq 1$. Then $p_j$ is a monotone decreasing function of $j$, $k_j > 0$ for $p < p_j$, $k_j = 0$ for $p = p_j$ and $k_j < 0$ for $p > p_j$. Let

$$\lambda_j^r := \begin{cases} \lambda_j & (1 < p \leq p_j), \\ 1 & (p_j < p < p_{j-1}), \\ \lambda_{j-1} & (p_{j-1} \leq p). \end{cases} \quad (3.20)$$

By the second identity of (3.17), and (3.19) together with the fact $k_{j-1}k_j < 0$ for $p_j < p < p_{j-1}$, we have the lower bound

$$L_j \geq \lambda_j^r. \quad (3.21)$$

In fact, this estimate is sharp: for $p \in (1, p_j) \cup (p_{j-1}, \infty)$, the ground state is obvious from the second identity of (3.17):

$$\begin{cases} L_j Q_j = \lambda_j Q_j, & (1 < p < p_j), \\ L_j Q_j^* = \lambda_j Q_j^* - 1, & (p_j < p < p_{j-1}), \\ L_j Q_j^* = \lambda_j Q_j^* - 1, & (p_{j-1} < p), \end{cases} \quad (3.22)$$

where we denote

$$Q_j := Q^{k_j}, \quad Q_j^* := Q^{-k_j}. \quad (3.23)$$

For $p \in [p_j, p_{j-1}]$, there is no ground state. Thus we have completely determined the ground state of $L_j$ for all $p > 1$. The complete spectrum, together with explicit eigenfunctions, are derived using the third identity of (3.18) as follows.

**Theorem 3.4** For any $j \in \mathbb{R}$ and $p > 1$, the point spectrum of $L_j$ consists of simple eigenvalues

$$\text{spec}_p(L_j) = \{\lambda_k \mid p < p_k, \ k \in \{j, j + 1, j + 2, \ldots\}\} \cup \{\lambda_k \mid p > p_k, \ k \in \{j - 1, j - 2, j - 3, \ldots\}\}, \quad (3.24)$$

and the eigenfunction for the eigenvalue $\lambda_k$ is given uniquely up to constant multiple by

$$\begin{cases} S_j^* \cdots S_{k-1}^* Q_k & (k \in \{j, j + 1, \ldots\}), \\ S_{j-1} \cdots S_{k+1} Q_k^* & (k \in \{j - 1, j - 2, \ldots\}), \end{cases} \quad (3.25)$$

each of which is a linear combination of

$$\begin{cases} Q_j, Q_{j+2}, \ldots Q_k & (k \in \{j, j + 2, \ldots\}), \\ Q_{j+1} R, Q_{j+3} R, \ldots Q_k R & (k \in \{j + 1, j + 3, \ldots\}), \\ Q_{j-1}^*, Q_{j-3}^*, \ldots Q_k^* & (k \in \{j - 1, j - 3, \ldots\}), \\ Q_{j-2}^* R, Q_{j-4}^* R, \ldots Q_k^* R & (k \in \{j - 2, j - 4, \ldots\}) \end{cases} \quad (3.26)$$

where $R := Q_j^2/Q_j$. 

24
Proof. The ground states have been determined. The third identity of (3.18) implies that (3.25) belong to the eigenspace of \( L_j \) with eigenvalue \( \lambda_k \). Moreover, each function is nonzero because \( S^*_k \) is injective for \( p < p_k \) and so is \( S_k \) for \( p_k < p \). Since \( S_j \) annihilates only the ground state \( Q_j \) for \( p < p_j \) and \( S^*_j \) annihilates only the ground state \( Q^*_j \) for \( p > p_j \), all the excited states of \( L_j \) for \( p < p_j \) are mapped injectively by \( S_j \) to bound states of \( L_{j+1} \), and for \( p > p_j \) by \( S^*_j \) to those of \( L_{j-1} \). Hence we have (3.24) and all the eigenvalues are simple because the ground states are so. (3.26) follows from the fact that \( S_j \) and \( S^*_j \) act on \( Q \) like \( C(a,j)R \), while \( S_j S_j - 1 \) and \( S^*_j - 1 S^*_j \) act on \( Q \) like \( C_1(a,j) + C_2(a,j)Q_{p-1} \). \( \square \)

3.4 Mirror conjugate identity

The following remarkable identity has application to estimating eigenvalues of \( L \) (see Section 3.6):

\[
S_j(L_{j-1} - \lambda_j)S^*_j = S^*_j(L_{j+2} - \lambda_j)S_j.
\] (3.27)

To prove this, start with the formula

\[
(\partial_x + R)(\partial_x^2 + V)(\partial_x - R) = \partial_x^4 + (-3R' - R^2 + V)\partial_x^2 + (-3R' - R^2 + V)'\partial_x - R''' - (VR)' - RR'' - R^2 V,
\] (3.28)

which implies that \((\partial_x + R)(\partial_x^2 + V_+)(\partial_x - R) = (\partial_x - R)(\partial_x^2 + V_-)(\partial_x + R)\) is equivalent to

\[
V_\pm = -R''/R \pm 3R' - R^2 + C/R.
\] (3.29)

Now set \( R := aQ'/Q \). Plugging the following identities

\[
R^2 = a^2(1 - \frac{2}{p+1}Q^{p-1}), \quad R' = -a\frac{p-1}{p+1}Q^{p-1},
\]

\[
R''/R = -\frac{(p-1)^2}{p+1}Q^{p-1}.
\] (3.30)

into (3.29), we get, for \( C = 0 \),

\[
V_\pm = -a^2 + \frac{2}{p+1}(a \pm (p-1))(a \pm (p-1)/2)Q^{p-1}.
\] (3.31)

Hence for \( a = k_j \) we have

\[
V_\pm = -k_j^2 + \frac{2}{p+1}k_{j \pm 2}k_{j \pm 1},
\] (3.32)

which gives the desired identity (3.27). The above proof also shows that \( L_{j-1} \) and \( L_{j+2} \) are the unique choice for the identity to hold with \( S_j \) (modulo a constant multiple of \( Q/Q_x \), which is singular).
3.5 Variational formulations for eigenvalues of $L$

We considered two variational formulations for nonzero eigenvalues of $L$ in general dimensions in Section 2.2. Here we present a new variational formulation for 1-D. Define the selfadjoint operator

$$H := SL_+ S^*.$$  \hspace{1cm} (3.33)

This is a fourth-order differential operator, with essential spectrum $[1, \infty)$. By a direct check, we have

$$HQ = SL_+ S^* Q = SL_+ (-2Q_x) = 0.$$  

Thus $Q$ is an eigenfunction with eigenvalue 0. Since $(Q, S^* f) = (SQ, f) = 0$ for any $f$, we have

$$\text{Range } S^* \perp Q.$$  \hspace{1cm} (3.34)

In particular, since $L_+|_{Q\perp}$ is nonnegative for $p \leq 5$ by Lemma 2.2, so is $H$.

**Lemma 3.5** The null space of $H$ is

$$N(H) = \text{span} \{Q, \delta_{pc} x Q\},$$

where, recall, $\delta_{pc}$ is 0 if $p \neq pc$, and 1 if $p = pc$.

**Remark.** Note that $\dim N(H) = 1 + \delta_{pc}$ which is different from $\dim N(L_{-1/2} L_+ L_{-1/2}) = 2 + \delta_{pc}$. We will show below that $H$ and $L_{-1/2} L_+ L_{-1/2}$ have the same nonzero eigenvalues.

**Proof.** If $H f = 0$, then $L_+ S^* f = -2cQ$ and $S^* f = cQ_1 + dQ_x$ for some $c, d \in \mathbb{R}$ by Lemma 2.1. We have $Q_1 \perp Q$ iff $p = pc = 5$. Thus, if $p \neq 5$, $c = 0$ by (3.34), and $S^* (f + d\frac{d}{2} Q) = 0$. We conclude $f = -\frac{d}{2} Q$.

When $p = 5$, we have $S^* x Q = -Q^{-1} \partial_x (Q x Q) = -2Q_1$. Thus $S^*(f + \frac{c}{2} Q_1 + \frac{d}{2} Q) = 0$ and $f = -\frac{c}{2} Q_1 - \frac{d}{2} Q$. \hfill \Box

Define eigenvalues of $H$ as follows:

$$\tilde{\mu}_j := \inf_{f \perp I, k < j} \frac{(f, H f)}{(f, f)}, \quad (j = 1, 2, 3, \ldots)$$  \hspace{1cm} (3.35)

with a suitably normalized minimizer denoted by $f_j$, if it exists. By standard variational arguments, if $\tilde{\mu}_j < 1$, then a minimizer $f_j$ exists. By convention, if $\mu_k$ is the first of the $\mu_j$’s to hit 1 (and so $f_k$ may not be defined), we set $\mu_j := 1$ for all $j > k$.

We can expand Theorem 2.5 to the following.

**Theorem 3.6 (Equivalence)** Let $n = 1$. Let $\mu_j$ be defined as in Theorem 2.5 and $\tilde{\mu}_j$ be defined by (3.35). Then $\mu_j = \tilde{\mu}_j$. When $\mu_j \neq 0$ and $\mu_j < 1$, the eigenfunctions of (2.19) and (3.35) can be chosen to satisfy

$$u_j = S^* f_j, \quad f_j = \frac{1}{\mu_j} SL_+ u_j.$$
Proof. First we establish the equivalence of nonzero eigenvalues. Suppose \( f = f_j \) is an eigenfunction of (3.35) with eigenvalue \( \tilde{\mu} \neq 0 \), then \( SL_+ S^* f = \tilde{\mu} f \). Let \( u := S^* f \neq 0 \) and apply \( S^* \) on both sides. By \( L_- = S^* S \) we get \( L_- L_+ u = \tilde{\mu} u \). Thus \( u \) is an eigenfunction satisfying (2.14) with \( \mu = \tilde{\mu} \). On the other hand, suppose \( u \) satisfies \( L_- L_+ u = \mu u \) with \( \mu \neq 0 \). Applying \( SL_+ \) on both sides and using \( L_- = S^* S \), we get \( SL_+ S^* S L_+ u = \mu SL_+ u \), i.e., \( H f = \mu f \) for \( f = \mu^{-1} SL_+ u \).

Now use Lemmas 2.3 and 3.5. If \( p \in (1, 5) \), then \( \mu_1 = \tilde{\mu}_1 = 0 \), corresponding to \( Q_x \) and \( Q \), and \( \mu_2 = \tilde{\mu}_2 > 0 \). If \( p = 5 \), then \( \mu_1 = \mu_2 = \tilde{\mu}_1 = \tilde{\mu}_2 = 0 \), corresponding to \( Q_x, Q_1 \), and \( Q, xQ \), and \( \mu_3 = \tilde{\mu}_3 = 1 \). If \( p \in (5, \infty) \), then \( \mu_1 = \tilde{\mu}_1 < 0 \), \( \mu_2 = \tilde{\mu}_2 = 0 \), corresponding to \( Q_x \) and \( Q \), and \( \mu_3 = \tilde{\mu}_3 = 1 \). We have shown \( \tilde{\mu}_j = \mu_j \). □

In the following we will make no distinction between \( \mu_j \) and \( \tilde{\mu}_j \). By the minimax principle, (3.35) has the following equivalent formulations:

\[
\mu_j = \inf_{\dim M = j} \sup_{f \in M} \frac{(f, H f)}{(f, f)} = \sup_{\dim M = j-1} \inf_{f \perp M} \frac{(f, H f)}{(f, f)}. \tag{3.36}
\]

Here \( M \) runs over all linear subspaces of \( L^2(\mathbb{R}) \) with the specified dimension.

### 3.6 Estimates of eigenvalues of \( \mathcal{L} \)

In this subsection we prove lower and upper bounds for eigenvalues of \( \mathcal{L} \), confirming some aspects of the numerical computations shown in Figure 1. Recall that, by Lemma 2.3, the first positive \( \mu_j \) is \( \mu_2 \) for \( p \in (1, p_c) \) and \( \mu_3 \) for \( p \in [p_c, p_{\text{max}}) \). The first theorem concerns upper bounds for \( \mu_1 \) and \( \mu_2 \).

![Figure 8: p vs. \( \mu_j \).](image)

**Theorem 3.7** Suppose \( n = 1 \) and \( 1 < p < \infty \).

(a) If \( p \neq 3 \), then \( \mu_2 \leq C_p \) for some explicitly computable \( C_p < 1 \). In particular \( f_2 \) exists.

(b) \( \mu_1 < 0 \) if and only if \( p > 5 \). For any \( C > 0 \), we have \( \mu_1(p) \leq -C p^3 \) for \( p \) sufficiently large.

27
Thus \( \mu_2 \) may not be less than 1.) This proves \( J_1 \) is less than 1 for \( k > 0 \). Also note that \( J_3 \) is odd and hence \( f \perp Q \), the 0-eigenfunction of \( H \). Since \( H = SL_+S^* \) and \( S^*S = L_- \), we have

\[
\mu_2 \leq \frac{(f, Hf)}{(f, f)} = \frac{(L_-Q^k, L_-L_-Q^k)}{(Q^k, L_-Q^k)}.
\]

By formulas (3.5) and (3.8),

\[
L_-Q^k = aQ^{k+p-1} + bQ^k, \quad a = f_p^-(k) = \frac{1}{p+1}(k-1)(2k+p+1), \quad b = 1 - k^2.
\]

\[
L_+Q^{k+p-1} = \sigma Q^{k+p-2} + dQ^{k+p-1},
\]

\[
\sigma = f_p(k + p - 1) = \frac{1}{p+1}(k+2p-1)(2k+p-3), \quad d = 1 - (k+p-1)^2.
\]

\[
L_+Q^k = cQ^{k+p-1} + bQ^k, \quad c = f_p(k) = \frac{1}{p+1}(k+p)(2k-p-1).
\]

Thus

\[
\frac{(f, Hf)}{(f, f)} = \frac{a^2\sigma J_3 + a(ad + bc + b\sigma)J_2 + b(ad + ab + bc)J_1 + b^2J_0}{aJ_1 + bJ_0}
\]

(3.37)

where

\[
J_m = \int_R Q^{2k+m(p-1)}(x) \, dx, \quad (m = 0, 1, 2, 3),
\]

which are always positive. If \( k \to 0^+ \), then \( J_m \) converges to \( \int_R Q^{m(p-1)} \, dx \) for \( m > 0 \), and \( J_0 = O(k^{-1}) \). The above quotient can be written as

\[
(3.37) = b^2 + \frac{J}{aJ_1 + bJ_0}
\]

where

\[
J = a^2\sigma J_3 + a(ad + bc + b\sigma)J_2 + b(ad + ab + bc)J_1.
\]

Note that \( J_m \big|_{k=0} = \left( \frac{p+1}{2} \right)^m \frac{2}{p+1} \int_R \sech^{2m}(y) \, dy \) with \( \int_R \sech^{2m}(y) \, dy = 2, \frac{4}{5}, \frac{16}{15} \) for \( m = 1, 2, 3 \), respectively. Also, as \( k \to 0^+, \ a \to -1, \ b \to 1, \ c \to -p, \ \sigma \to \frac{2(p-1)(p-3)}{p+1} \), and \( d \to 1 - (p - 1)^2 \). Direct calculation shows

\[
\lim_{k \to 0^+} J = -\frac{2}{15(p-1)} (p+1)^2(p-3)^2.
\]

Also note \( b^2 < 1 \) for \( k > 0 \). Thus, if \( 1 < p < \infty \) and \( p \neq 3 \), then \( J < 0 \) and the quotient (3.37) is less than 1 for \( k \) sufficiently small. (If \( p = 3 \), the sign of \( J \) is unclear and (3.37) may not be less than 1.) This proves \( \mu_2 < 1 \) and provides an upper bound less than 1 for \( \mu_2 \). It also implies the existence of \( f_2 \). This establishes statement (a).
For statement (b), the fact that $\mu_1 < 0$ if and only if $p > 5$ is part of Lemma 2.3. We now consider the behavior of $\mu_1$ for $p$ large. Fix $k > 1$ to be chosen later. As $p \to \infty$,

$$J_m = \left( p + 1 \right) \frac{2}{p - 1} \cdot \frac{2}{p - 1} \int_\mathbb{R} (\text{sech} x) \frac{2k + m}{2k + m} \, dx \sim C_m p^{m-1},$$

with $C_m = 2^{1-m} \int_\mathbb{R} (\text{sech} x)^2 \, dx = 2 \cdot \frac{2}{3} \cdot \frac{4}{15}$ for $m = 1, 2, 3$, respectively, and

$$a \sim k - 1, \quad b = 1 - k^2, \quad c \sim -p, \quad d \sim -p^2.$$ 

Thus, by (3.37),

$$\frac{(f, Hf)}{(f, f)} \sim \frac{a \sigma J_3 + a d J_2}{J_1} \sim \frac{1 - k}{15} p^{3} \quad \text{as} \quad p \to \infty.$$ 

By choosing $k > 1$ sufficiently large, we have shown that for any $C$, $\mu_1 \leq -Cp^{3}$ for $p$ sufficiently large. □

The next theorem bounds eigenvalues of $L$ by eigenvalues of $L_+$ and $L_-$. Recall $p_j$ and $\lambda_j(p)$ are defined in (3.4) and (3.3).

**Theorem 3.8 (Interlacing of eigenvalues)** Fix $k \geq 1$ and $p \in [p_{k+1}, \, p_{k+2}]$ where, recall, $p_j = \frac{j+1}{j-1}$. Let $\lambda_j(p) = 1 - \frac{1}{2} \left[ (\lambda_j + 1) - (p-1) \right]^2$ be as in (3.3) and so $\lambda_{k+1} < 1 \leq \lambda_{k+2}$. For the eigenvalues $\mu_j$ defined by (3.35), we have

$$\lambda_{j+1}^2(p) < \mu_{j+1}(p) < \lambda_{j+2}^2(p), \quad (1 \leq j < k); \quad \lambda_{k+1}^2(p) < \mu_{k+1}(p) \leq 1. \quad (3.38)$$

In particular, there are $K$ simple eigenvalues $\mu_2, \ldots, \mu_{K-1}$ in $(0, 1)$ where $K = k$ if $\mu_{k+1} < 1$ and $K = k - 1$ if $\mu_{k+1} = 1$. Moreover, $K$ is always 1 when $k = 1$. Finally,

$$\mu_2 \geq \begin{cases} 
\lambda_2 \lambda_3 & (1 < p \leq 2), \\
\lambda_2 & (2 < p < 5), 
\end{cases} \quad \mu_3 \geq \begin{cases} 
\lambda_3 \lambda_4 & (1 < p \leq 5/3), \\
\lambda_3 & (5/3 < p \leq 2), \\
1 & (2 < p < \infty), 
\end{cases}$$

$$\mu_1 \geq -\frac{1}{16} \left( p - 1 \right)^3 \left( p - 5 \right) \quad (5 \leq p < \infty).$$

**Remark 3.9** In view of the above lower bounds for $\mu_2$ and $\mu_3$, we conjecture that

$$\mu_{j+1} \geq \lambda_{j+1} \lambda_{j+2} \quad (1 < p < p_{j+2}); \quad \mu_{j+1} \geq \lambda_{j+1} \quad (p_{j+2} \leq p < p_{j+1}). \quad (3.39)$$

This is further confirmed numerically for $j = 3, 4, 5$ (see Figure 9). Note that $\lim_{p \to p_{j+1}-} \frac{\lambda_{j+1}}{\mu_{j+1}} = 1$ because both $\lambda_{j+1}$ and $\mu_{j+1}$ converge to 1. It also seems that $\frac{\lambda_{j+1} \lambda_{j+2}}{\mu_{j+1}}$ has a limit as $p \to 1+$, but it is not clear although we have (3.38) and $\lambda_j = (j-1)(p-1) + O((p-1)^2)$ as $p \to 1+.$
Figure 9: $p$ vs. $f_j$ for $j = 1, \ldots, 5$, where $f_j(p) = \frac{\lambda_{j+1} \lambda_{j+2}}{\mu_{j+1}}$ for $1 < p < p_{j+2}$ and $f_j(p) = \frac{\lambda_{j+1}}{\mu_{j+1}}$ for $p_{j+2} \leq p < p_{j+1}$.

**Proof.** We first prove the upper bound: For $j < k$, use the test functions $S\psi_2, S\psi_3, \ldots, S\psi_{j+2}$ (we cannot use $S\psi_1$ since it is zero). Recall $L_- \psi_m = \lambda_m \psi_m$. Let $a = (a_2, \ldots, a_{j+2})$ vary over $\mathbb{C}^{j+1} \setminus \{0\}$. By equivalent definition (3.36), $H = S L_+ S^*$, $L_- = S^* S$, and the orthogonality between the $\psi_m$'s, we have

\[
\mu_{j+1} \leq \sup_a \frac{\langle \sum_m a_m S\psi_m, H \sum_\ell a_\ell S\psi_\ell \rangle}{\langle \sum_m a_m S\psi_m, \sum_\ell a_\ell S\psi_\ell \rangle} = \sup_a \frac{\langle \sum_m a_m \psi_m, L_- L_+ L_- \sum_\ell a_\ell \psi_\ell \rangle}{\langle \sum_m a_m \psi_m, L_- \sum_\ell a_\ell \psi_\ell \rangle} \\
\leq \sup_a \frac{\langle \sum_m a_m \psi_m, L_- L_- \sum_\ell a_\ell \psi_\ell \rangle}{\langle \sum_m a_m \psi_m, L_- \sum_\ell a_\ell \psi_\ell \rangle} = \sup_a \frac{\sum_m |a_m|^2 \lambda_m^3}{\sum_m |a_m|^2 \lambda_m} \\
\leq \max_{m=2, \ldots, j+2} \lambda_m^2 = \lambda_{j+2}^2.
\]

Since $\mu_{j+1} \leq \lambda_{j+2}^2 < 1$, it is attained at some function, for which the second inequality above cannot be replaced by an equality sign. Thus $\mu_{j+1} < \lambda_{j+2}^2$.

For the lower bound of eigenvalues, we use only the special case $j = 1$ of (3.27):

\[
H = S L_+ S^* = S L_0 S^* = S^* L_3 S.
\]  

In particular, we have for $1 < p < 3$,

\[
H \geq S^* L_2 S = S^* S S^* S = L_1^2 = L_1^2,
\]

which implies that

\[
\lambda_{j+1}^2 \leq \mu_{j+1} \quad (1 < p < 3)
\]

(and again, equality is impossible).
For the second eigenvalue $\mu_2$, we can get a more precise estimate by using (3.21) for $L_3 \geq \lambda_3'$ together with
\[ L_1|_{Q^\perp} \geq \lambda_2', \]
which follows from $\text{spec}(L_1)$. Combining these estimates, we have for any $f \perp Q$ and $p < 5$,
\[ (Hf, f) \geq \lambda_3'(Sf, Sf) \geq \lambda_3'\lambda_2'(f, f), \]
which implies that $\mu_2 \geq \lambda_3'\lambda_2'$, i.e.,
\[ \mu_2 \geq \begin{cases} 
\lambda_2\lambda_3 & (1 < p \leq 2), \\
\lambda_2 & (2 < p < 5) 
\end{cases} \]
For $p > 3$, we have $L_3 \geq \lambda_2 = -(p - 1)(p - 5)/4$ and
\[ L_3 - L_2 \geq -(p - 1)(p - 3)/2 =: -a. \]
Hence for any $t \in [0, 1]$, we have
\[ L_3 \geq tL_2 - at + (1 - t)\lambda_2. \]
and so for $b > 0$, we have
\[ (Hf, f) + b(f, f) \geq (S^*(tL_2 - at + (1 - t)\lambda_2)Sf, f) + b(f, f) = t\|L_1f\|^2 - (at - (1 - t)\lambda_2)(L_1f, f) + b\|f\|^2, \]
which is nonnegative if
\[ b \geq (at - (1 - t)\lambda_2)^2/(4t), \]
whose infimum is attained at $t = -\lambda_2/(a + \lambda_2) = (p - 5)/(p - 1) \in (0, 1)$ for $p > 5$. Plugging this back in, we obtain the lower bound
\[ \mu_1 \geq \lambda_2(a + \lambda_2) = -\frac{1}{16}(p - 1)^3(p - 5) \quad (p > 5). \]
We have a similar bound on $\mu_3$ by using the even-odd decomposition $L^2(\mathbb{R}) = L^2_{\text{ev}}(\mathbb{R}) \oplus L^2_{\text{od}}(\mathbb{R})$. Let $\psi_j, \xi_j$ be the eigenfunction of $L_1$ and $L_3$ such that
\[ L_1\psi_j = \lambda_j\psi_j, \quad L_3\xi_j = \lambda_j\xi_j. \]
$\psi_j$ starts from $j = 1$ and $\xi_j$ starts with $j = 3$. They are even for odd $j$ and odd for even $j$. For any even function $f \perp Q = \psi_1, Sf$ is odd and so we have $f \perp \psi_1 = Q, \psi_2$ and $Sf \perp \xi_3$. Hence by $\text{spec}(L_3)$ and $\text{spec}(L_1)$, we have
\[ (Hf, f) = (L_3Sf, Sf) \geq \tilde{\lambda}_4(Sf, Sf) = \tilde{\lambda}_4(L_1f, f) \geq \tilde{\lambda}_4\lambda_3(f, f), \]
where we denote
\[ \tilde{\lambda}_j := \begin{cases} 
\lambda_j & (1 < p < p_j), \\
1 & (p_j < p). 
\end{cases} \]
Thus the second eigenvalue of $H$ on $L^2_{ev}$ is $\geq \tilde{\lambda}_4\tilde{\lambda}_3$. Next for any odd function $f \perp \psi_2$, we have $f \perp \psi_1, \psi_2, \psi_3$. Hence we have

$$(Hf, f) = (L_3sf, sf) \geq \lambda_3^s(Sf, sf) = \lambda_3^s(L_1f, f) \geq \lambda_3^s\tilde{\lambda}_4(f, f).$$ (3.54)

Similarly, every odd function $f \perp S^*\xi_3$ satisfies $f \perp \psi_1$ and $Sf \perp \xi_3, \xi_4$, so

$$(Hf, f) \geq \tilde{\lambda}_5\tilde{\lambda}_2(f, f).$$ (3.55)

Hence the second eigenfunction on $L^2_{od}$ is $\geq \max(\tilde{\lambda}_4\lambda_3^s, \tilde{\lambda}_5\lambda_2) \geq \tilde{\lambda}_4\lambda_3$. Therefore we have

$$\mu_3 \geq \tilde{\lambda}_3\lambda_4, \text{ i.e.,}$$

$$\mu_3 \geq \begin{cases} 
\lambda_3\lambda_4 & (1 < p < 5/3), \\
\lambda_3 & (5/3 < p < 2), \\
1 & (2 < p). 
\end{cases}$$ (3.56)

This argument, however, does not yield any useful estimates for the higher $\mu_j$. $\square$

### 3.7 Resonance for $p = 3$

In the theory of dispersive estimates for the linear Schrödinger evolution, it is important to know whether or not the endpoints of the continuous spectrum of the linear operator are eigenvalues or resonances. For our $L$, the endpoints are $\lambda = \pm i$. Resonance here refers to a function $\phi$ which satisfies the eigenvalue problem locally in space with eigenvalue $i$ or $-i$, but which does not belong to $L^2(\mathbb{R}^n)$. For dimension $n = 1$, one requires $\phi \in L^\infty(\mathbb{R})$. (Note for comparison’s sake that in one dimension, the operator $-d^2/dx^2$ has a resonance – corresponding to the constant function – at the endpoint 0 of its continuous spectrum.)

Before we made the numerical calculation, we did not expect to see any resonance. However, from Figure 1, one sees that $\kappa = \sqrt{\mu_2}$ converges to 1 as $p \to 3$. What does the point $\kappa = 1$ at $p = 3$ correspond to? A natural conjecture is that it is a resonance or an eigenvalue, since the $p = 3$ case is well-known to be completely integrable and special phenomena may occur.

This is indeed the case since we have the following solution to the eigenvalue problem (2.12) when $p = 3$,

$$\phi = \begin{bmatrix} 1 - Q^2 \\ i \end{bmatrix}, \quad \lambda = i.$$ (3.57)

It is clear that $\phi \in L^\infty(\mathbb{R})$ but $\phi \not\in L^q(\mathbb{R})$ for any $q < \infty$.

Let $u_p(x)$ denote the real-valued (and suitably normalized) solution of (2.14) corresponding to $\mu = \mu_2$. It is the first component of the eigenfunction of (2.12). A natural question is: does $u_p(x)$ converge in some sense to $u_3(x) := 1 - Q^2(x)$ as $p \to 3$? Since $u_p - u_3$ is not in $L^q(\mathbb{R})$ for all $q \in [1, \infty)$, it seems natural to measure the convergence in the following weighted norm,

$$\|f\|_w := \int_\mathbb{R} w(f)^2(x) \, dx,$$
where a weighting operator $w$ is defined by $w(f)(x) := f(x) \sqrt{1+x^2}$. This de-emphasizes the value of $u_p - u_3$ for $x$ large, and so it should converge to 0 as $p$ goes to 3. This is confirmed numerically as follows.

Let $u_3 := 1 - Q^2$ and $\delta := \|u_3\|_w$. In Section 4 we will propose a numerical method to solve for the eigenpair $\{\lambda, [u_p(x), \ w_p(x)]^T\}$ of (2.12) corresponding to $\mu_2 = -\lambda^2$. Renormalize $u_p(x)$ for $p \neq 3$ so that it is real-valued, $u_p(0) < 0$, and $\|u_p\|_w = \delta$. In Figure 10(c) we plot $u_3$ in a large interval $|x| < 130$ with $\delta = 1.3588$. According to the numerical method in Section 4, we get $u_{2.8}, u_{2.9}, u_{3.1}$ and $u_{3.2}$ plotted in Figure 10(a), (b), (d) and (e), respectively. The vertical range is roughly $[-1, 1]$. In Figure 10(f)–(j) we plot $w(u_p)$ for $p = 2.8, 2.9, 3, 3.1$ and 3.2, for $|x| < 130$ and vertical range $[-1, 0.5]$.

![Figure 10: $u_p(x)$ & $w(u_p)(x)$ for $p = 2.8, 2.9, 3, 3.1$ and 3.2.](image)

In Figure 11 we plot $p$ vs. $\|u_p - u_3\|_w$ and observe that $u_p(x)$ converge to $u_3(x)$ in the weighted norm $\|\cdot\|_w$ as $p \to 3$. In the numerical calculation for Figure 11, our increment for $p$ is 0.01.

![Figure 11: $p$ vs. $\|u_p - u_3\|_w$.](image)
Remark 3.10 For the operators $L_+ L_-$ and $L_- L_+$, and in general 4-th order operators, it seems difficult to exclude the possibility that $\mu = 1$ is an eigenvalue. Consider the following example. Let $\tilde{H} := (L_+)^2$ with $p = \sqrt{8} - 1$. Note $-1$ is an eigenvalue of $L_+$ when $p = \sqrt{8} - 1$. Hence 1 is an eigenvalue of $\tilde{H}$, at the endpoint of its continuous spectrum.

It would be interesting to prove the above convergence analytically and characterize the leading order behavior near $p = 3$ as we did in Theorem 2.6.

4 Numerical method for the spectra of the ground states

In this section we propose a numerical method to compute the spectrum of the linear operator $L$ defined by (1.8) for $p > 1$ and space dimension $n \geq 1$. There are two main steps in this method. First, we will solve the nonlinear problem (1.3) for $Q$: we will discretize it into a nonlinear algebraic equation, and then solve it by an iterative method. Second, we will compute the spectrum of $L$: we will discretize the operator $L$ into a large-scale linear algebraic eigenvalue problem and then use implicitly restarted Arnoldi methods to deal with this problem.

Hereafter, we use the bold face letters or symbols to denote a matrix or a vector. For $A \in \mathbb{R}^{M \times N}$, $q = (q_1, \ldots, q_N)^\top \in \mathbb{R}^N$, $q^{\circ p} = q \circ \cdots \circ q$ denotes the $p$-time Hadamard product of $q$, and $[q] := \text{diag}(q)$ the diagonal matrix of $q$.

Step I. We first discretize equation (1.3) into a nonlinear algebraic equation and consider it on an $n$-dimensional ball $\Omega = \{x \in \mathbb{R}^n : |x| \leq R, R \in \mathbb{R}\}$. We rewrite the Laplace operator $-\Delta$ in the polar coordinate system with a Dirichlet boundary condition. Based on the recently proposed discretization scheme [15], the standard central finite difference method, we discretize $-\Delta q(x)$ into

\[
Aq = A[q_1, \ldots, q_N]^\top, \quad A \in \mathbb{R}^{N \times N},
\]  

(4.1)

where $q$ is an approximation of the function $Q(x)$. The matrix $A$ is irreducible and diagonally-dominant with positive diagonal entries. The discretization of the nonlinear equation (1.3) can now be formulated as the following nonlinear algebraic equation,

\[
Aq + q - q^{\circ p} = 0.
\]  

(4.2)

We introduce an iterative algorithm [12] to solve (4.2):

\[
A\tilde{q}_{j+1} + \tilde{q}_{j+1} = q_j^{\circ p},
\]  

(4.3)

where $\tilde{q}_{j+1}$ and $q_j$ are the unknown and known discrete values of the function $Q(x)$, respectively. The iterative algorithm is shown in Algorithm 1.

Algorithm 1. Iterative Algorithm for Solving $Q(x)$.

Step 0 Let $j = 0$.

Choose an initial solution $\tilde{q}_0 > 0$ and let $q_0 = \frac{\tilde{q}_0}{\|\tilde{q}_0\|_2}$.
Step 1 Solve the equation (4.3), then obtain $\tilde{q}_{j+1}$.

Step 2 Let $\alpha_{j+1} = \frac{1}{\|q_{j+1}\|_2}$ and normalize $\tilde{q}_{j+1}$ to obtain $q_{j+1} = \alpha_{j+1} \tilde{q}_{j+1}$.

Step 3 If (convergent) then

Output the scaled solution $(\alpha_{j+1})^{\frac{1}{p-1}} q_{j+1}$. Stop.

else

Let $j := j + 1$.

Goto Step 1.

end

If the components of $q_0$ are nonnegative, this property is preserved by each iteration $q_j$, and hence also by the limit vector if it exists (see [12, Theorem 3.1]). The convergence of a subsequence of this iteration method to a nonzero vector is proved in [12, Theorem 2.1]. Although the convergence of the entire sequence is not proved, it is observed numerically to be very robust. See Chen-Zhou-Ni [5] for a survey on numerically solving nonlinear elliptic equations.

**Step II.** Next we discretize the operator $L$ of (1.10) into a linear algebraic eigenvalue problem:

$$L \begin{bmatrix} u \\ w \end{bmatrix} = \lambda \begin{bmatrix} u \\ w \end{bmatrix},$$

(4.4)

where

$$L = \begin{bmatrix} 0 & A + I - \|q\| \\ -A - I + \|p \| & 0 \end{bmatrix},$$

$\gamma = p - 1$, $u = (u_1, \ldots, u_N)^\top \in \mathbb{R}^N$, $w = (w_1, \ldots, w_N)^\top \in \mathbb{R}^N$, and $q$ is the output of the previous step, and satisfies the equation in (4.2). We use ARPACK [17] in MATLAB version 6.5 to deal with the linear algebraic eigenvalue problem (4.4) and obtain eigenvalues $\lambda$ of $L$ near the origin for $p > 1$ and space dimension $n \geq 1$. Furthermore, the eigenvectors of $L$ can be also produced.

The Step II above can in principle be used to compute all eigenfunctions in $L^2(\mathbb{R}^n)$. However, in producing Figures 2–7, we look for eigenfunctions of the form $\phi(r)e^{im\theta}$. These problems can be reformulated as 1-D eigenvalue problems for $\phi(r)$, which can be computed using the same algorithm and MATLAB code. This dimensional reduction saves a lot of computation time and memory. Even with this dimensional reduction, and applying an algorithm for sparse matrices, the computation is still very heavy, and we cannot compute all eigenvalues in one step. We can only compute a portion of them each time.

5 **Excited states with angular momenta**

In this section we consider excited states with angular momenta in $\mathbb{R}^n, n \geq 2$. Let $k = \lfloor n/2 \rfloor$, the largest integer no larger than $n/2$. For $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$, use polar coordinates $r_j$
and $\theta_j$ for each pair $x_{2j-1}$ and $x_{2j}$, $j = 1, \ldots, k$. P. L. Lions [16] considers solutions of the form

$$Q(x) = \phi(r_1, r_2, \ldots, r_k, x_n) e^{i(m_1 \theta_1 + \cdots + m_k \theta_k)}, \quad m_j \in \mathbb{Z}.$$  

The dependence of $\phi$ in $x_n$ is dropped if $n$ is even. He proves the existence of energy minimizing solutions in each such class.

For the simplest case $n = 2$, $Q(x) = \phi(r) e^{im\theta}$ and, by (1.3), $\phi = \phi(r)$ satisfies

$$-\phi'' - \frac{1}{r}\phi' + \frac{m^2}{r^2} \phi + \phi - |\phi|^{p-1}\phi = 0, \quad (r > 0). \quad (5.1)$$

The natural boundary conditions are

$$\lim_{r \to 0} r^{-m} \phi(r) = \alpha, \quad \lim_{r \to 0} r^{-m+1} \phi'(r) = m\alpha, \quad \lim_{r \to \infty} \phi(r) = 0, \quad \text{for some } \alpha \geq 0. \quad (5.2)$$

for some $\alpha \geq 0$. One can choose $\phi(r)$ real-valued. It is shown by Iaia-Warchall [13] that (5.1)–(5.2) has countably infinite many solutions, denoted by $\phi_{m,k,p}(r)$, each has exactly $k$ positive zeros. They correspond to “$m$-equivariant” nonlinear bound states of the form

$$Q_{m,k,p} = \phi_{m,k,p}(r) e^{im\theta}, \quad (k = 0, 1, 2, \ldots). \quad (5.3)$$

Note that $Q_{m,k,p}$ are radial if and only if $m = 0$, and the ground state $Q = Q_{0,0,p}$ is considered in the previous sections. The uniqueness question of $\phi_{m,k,p}(r)$ is not addressed in [13]. It is proved for the case $k = 0$ in [18].

Mizumachi [18]–[21] considered the stability problem for these solutions. He showed that

1. Under $m$-equivariant perturbations of the form $\varepsilon(r)e^{im\theta}$, $Q_{m,0,p}$ are stable for $1 < p < 3$ and unstable for $p > 3$;
2. Under general perturbations, $Q_{m,k,p}$ are unstable for $p > 3$ for any $k$;
3. linear (spectral) instability implies nonlinear instability; (it can be also obtained by extending the results in [26] to higher dimensions using the method of [1]);
4. For fixed $p > 1$, if $m > M(p)$ is sufficiently large, $Q_{m,k,p}$ are linearly unstable and its linearized operator has a positive eigenvalue.

We are most interested in the last result. Intuitively, for $1 < p < \infty$, $Q_{m,k,p}$ should be unstable for all $(m, k) \neq (0, 0)$ since they are excited states. The results of our numerical computations of the spectra of $\mathcal{L}$ for $m = 1, 2$ and various $p$, shown in Figures 12–15, indicate that this is indeed the case for $Q_{1,0,p}$ and $Q_{2,0,p}$. Moreover, it seems that, as $p$ varies,

1. For $m = 1$, there is always at least a pair of nonzero real eigenvalues. This is not the case for $m = 2$. For $m = 2$, there are always complex (i.e. with non-zero real and imaginary parts) eigenvalues;
2. As \( p \) varies, two pairs of purely imaginary eigenvalues may collide on the imaginary axis away from zero, and then bifurcate to 4 complex eigenvalues which are neither real nor purely imaginary.

3. These complex eigenvalues may later collide again and become purely imaginary eigenvalues.

Unfortunately these numerical figures, obtained via MatLab, are not detailed enough to support points 2 and 3 above. The true picture may be more complicated. We plan to develop a numerical code using Fortran and apply a numerical algorithm tracking specifically those complex eigenvalues in a forthcoming paper. It would be also interesting to prove some of the statements analytically.

We now explain our numerical method. There are two steps: First, compute \( \phi_{m,0,p}(r) \). Second, compute the spectra of the discretized linearized operator around \( Q_{m,0,p} \).

**Step 1.** Compute \( \phi(r) = \phi_{m,0,p}(r) \). It is energy minimizing among all solutions of (5.1)–(5.2) for fixed \( m, p \), and it is positive for \( r > 0 \). Since our algorithm in the previous section is applicable to all positive (ground state) solutions, we can use it to calculate the discretized vector of \( \phi(r) \) with a small change of the code.

**Step 2.** Compute the spectra of the discretized linearized operator. The linearized operator \( L \) has a slightly different form than (1.9) because \( Q = \phi_{m,0,p}(r)e^{im\theta} \) is no longer real. With the same ansatz (1.6)–(1.7), the linearized operator \( L \) has the form

\[
Lh = i \left( \Delta h - h + \frac{p+1}{2} |Q|^{p-1}h + \frac{p-1}{2} |Q|^{p-3}Q^2 \bar{h} \right).
\]

In vector form and writing \( Q = \phi_{m,0,p}(r)e^{im\theta} = \phi_1 + i\phi_2 \) with \( \phi_1 \) and \( \phi_2 \) real, we have

\[
L = \begin{bmatrix} 0 & -\Delta + 1 \\ \Delta - 1 & 0 \end{bmatrix} + |\phi|^{p-3} \begin{bmatrix} -(p-1)\phi_1\phi_2 & -\phi_1^2 - p\phi_2^2 \\ p\phi_1^2 + \phi_2^2 & (p-1)\phi_1\phi_2 \end{bmatrix}.
\]

Although this is slightly more complicated than (1.9), our numerical scheme in previous section still works. In fact, our numerical scheme uses polar coordinates and the potential part above has the simple form

\[
|\phi_{m,0,p}(r)|^{p-1} \begin{bmatrix} -(p-1)\cos\sin & -\cos^2 - p\sin^2 \\ p\cos^2 + \sin^2 & (p-1)\cos\sin \end{bmatrix} (m\theta).
\]

**Remark 5.1**

1. One expects more eigenvalues as one decreases \( p \), and hence a smaller mesh and more computation time are required to compute the spectra.

2. For \( m \geq 0 \) and \( k > 0 \), the functions \( \phi_{m,k,p}(r) \) are sign-changing and cannot be numerically calculated using the method described in the previous section. Hence we cannot compute the spectra of \( L \) for \( Q_{m,k,p} \). We will pursue this problem elsewhere.
Acknowledgments

Special thanks go to Wen-Wei Lin, whose constant advice and interest were indispensable for this project. We thank V.S. Buslaev, Y. Martel, F. Merle, T. Mizumachi, C. Sulem, and W.C. Wang for fruitful discussions and providing many references to us. Part of the work was done when Nakanishi was visiting the University of British Columbia, Vancouver, and when Tsai was visiting the National Center for Theoretical Sciences, Hsinchu & Taipei. The hospitality of these institutions are gratefully acknowledged. The research of Chang is partly supported by National Science Council in Taiwan. The research of Gustafson and Tsai is partly supported by NSERC grants nos. 22R80976 and 22R81253. The research of Nakanishi is partly supported by the JSPS grant no. 15740086.
